## ACKNOWLEDGEMENT

I thank the Thailand Research Fund for a scholarship through the Royal Golden Jubilee Ph.D. Program (RGJ-Grant No. PHD/0014/2556).

The dissertation would not have been accomplished without help from several people. First of all, I would like to thank Professor Dr. Sampan Rittidech, the chairperson of my advisory committee, for inspiration, knowledge, experience, research perspective and valuable suggestions that allowed this study to be completed. I would also like to thank my advisory committee, Assistant Professor Dr. Teerapat Chompookham and Professor Dr. Yulong Ding and also Assistant Professor Dr. Thanya Parametthanuwat, my external examiner for many helpful suggestions.

I am very thankful to all the students of the Heat Pipe and Thermal Tools Design Research Unit (HTDR), Mahasarakham University, Thailand, both my friends and colleagues, for all their help.

I would also like to thank to all the students in the Yulong Laboratory, School of Chemical Engineering, University of Birmingham.

I was very fortunate to have many friends, both within and outside the Faculty of Engineering, during my doctoral life. I thank them all for being very supportive. I also owe thanks and many other people in a long list that might take several pages for support in many ways. Finally, I would like to express my deepest gratefulness to Mr. Sutut, Mrs. Yupawan, Mr. Weera, Mr. Bua and Mrs. Buapan Siriwan, for valuable love, care, help, willpower and support in my whole life.

### ABSTRACT

This thesis studied heat transfer with a numerical model and experimental evaluation of a helical oscillating heat pipe (HOHP). Firstly, I created a numeric model of the HOHP to predict the time required to reach the steady state temperature, the heat transfer of the HOHP and the heat transfer of the HOHP heat exchanger under transient conditions. Secondly, I measured the temperature at the pipe wall and evaluated the heat transfer rate and compared them with the numeric model. Thirdly, I applied results from the numeric model and experiments to select the parameters to obtain the best heat transfer rates for constructed the HOHP heat exchanger.

The model allowed determination of the temperature profiles at the pipe wall, heat transfer profiles of the HOHP itself and heat transfer profiles of the HOHP heat exchanger. The governing equation for the pipe wall is the conduction equation, and the governing equations for the vapor core are the continuity, the momentum and the energy equations. All of the governing equations were solved numerically using finite difference methods. The time required to reach the steady state temperature of the pipe wall, the heat transfer of the HOHP and the heat transfer of the HOHP heat exchanger were determined in this part. The results show that a temperature for the evaporator section of 60°C had a time to the steady state temperature and steady state heat transfer that was less than the temperatures for the evaporator section of 70 and 80°C. A temperature of 80°C for the evaporator section had the highest heat transfer of the HOHP and the HOHP heat exchanger.

The second part measured the temperature profiles of the pipe wall and the heat transfer profiles of the HOHP. The HOHP was constructed from copper tubes and the

working fluids were water, ethanol and R11; the temperatures of the evaporator section were 60, 70 and 80°C; the inner diameters of the pipe were 1.6, 1.8 and 2.0 mm; the thickness was 0.5 mm; the total lengths of the pipe at the evaporator and the condenser sections were 850 mm; length of the adiabatic section was 50 mm; the temperature of the water in the condenser section was 20°C; the mass flow rate of the water at the inlet of the evaporator and the condenser sections was 0.25 kg/min; the filling ratio was 80% with respect to the total volume of the HOHP; inclination angle was 90 degrees from the horizontal; the evaporator and the condenser sections had five coils; the diameter of the coil was 50 mm; and pitch was 10 mm. The time required to reach the steady state temperature of the pipe wall and the heat transfer of the HOHP were measured in this part and the results from the experimental evaluation of the HOHP were compared with the model from the first part. The results show that R11 working fluid had the highest heat transfer for the HOHP, the temperature for the evaporator section of 80°C had the highest heat transfer for the HOHP and 2.0 mm inner diameter had the highest heat transfer for the HOHP. The results from the experimental evaluation and those from the model were in good agreement.

The third part shows the heat transfer of the HOHP heat exchanger from the experimental evaluation. The HOHP heat exchanger was constructed from copper tubes and the parameters in the experiment were the same as the HOHP experiment and the selected working fluid, temperature, inner diameter of pipe and total lengths of pipe at the evaporator and the condenser sections were those provided the best heat transfer from the scope of the experiment. The mass flow rate of the water at the evaporator and the condenser sections was 1.5 kg/min and the HOHP heat exchanger used a counter flow arrangement. The time required to reach the steady state heat transfer for the HOHP heat exchanger was determined in this part and found to be in good agreement with predictions from the model and experiments.

**Key words:** Helical oscillating heat pipe; Mathematical model; Heat transfer; Heat exchanger

# CHAPTER 1

## INTRODUCTION

### 1.1 Background

A heat pipe has a high heat transfer. In 1972, the idea of the heat pipe was presented by R.S. Gaugler; however, in 1960, G.M. Grover had invented the heat pipe. Since then, there has been development of the heat transfer properties of the heat pipe and the heat pipe is widely known in the present. First, heat pipes are used in space technology, satellites and nuclear power plants and in the present the heat pipe can be used to reduce the heat in electronic devices, such as computers, or used to save energy and for heat exchange in industry. A heat pipe has three sections: the evaporator, the adiabatic and the condenser sections. The heat pipe uses the principles of heat transfer from the state change of the working fluid within the pipe, which does not require external energy. The heat pipe has the principle of the boiling of the working fluid, when the working fluid within the evaporator section receives heat it will evaporate and reduce the heat at the condenser section. The working fluid will form condensation and the heat from the condensation will be lost to the environment, then the working fluid will be liquid and flow to the evaporator section by gravity [1]. In the present, the heat pipe is appropriate for use but the effectiveness of them needs increasing, so the heat pipe has changed schematically quickly. The helical oscillating heat pipe (HOHP) is a heat pipe of another type, for use to solve the problems from above.

The HOHP is complex, and needs to be analyzed by a mathematical model. The mathematical model uses math to describe the system by assumptions, or set of boundary conditions in the analysis. To predict the behavior of the heat transfer of the heat pipe, commonly mathematical methods are used to solve the problems. The analysis for the solution will use numerical methods to solve the engineering problem by using a computer program for the calculation. Using a computer programming in the calculation will give the similar value as with the true value, mostly. The finite difference method is a numerical method used to solve the differential equations and it is common for the analysis to solve engineering and science problems, due to it being

able to simulate the structure or the workpiece complexity. In using the finite difference method, we will use a computer for the calculation to provide a fast calculation.

However, at present, the HOHP does not have the background information to analyze it in depth. Which means no researchers have created a mathematical model to predict the performance of the HOHP.

Therefore, this research aims to develop a mathematical model of a helical oscillating heat pipe and the application of the finite difference method to solve the governing equations for the transient condition by using a computer program for the calculation.

## **1.2 Objectives of study**

1.2.1 To create a mathematical model for the prediction of the heat transfer of a HOHP.

1.2.2 To compare the results from the mathematical model and an experiments.

1.2.3 To design and create a heat exchanger.

1.2.4 To compare the performance of the heat exchanger from the model with the experiments.

## **1.3 Scope of study**

### **1.3.1 Scope of mathematical model**

1.3.1.1 Apply the numerical method for the mathematical model of the HOHP.

1.3.1.2 Apply the computer program to solve the mathematical model of the HOHP.

1.3.1.3 Analyze the HOHP in 1-D.

### 1.3.2 Scope of experimental evaluation

#### 1.3.2.1 Independent parameters

- 1) Working fluids were water, ethanol and R11.
- 2) Temperatures of the evaporator section were 60, 70 and 80°C.
- 3) HOHP was made from copper pipe with the inner diameters of 1.6, 1.8 and 2.0 mm and thickness was 0.5 mm.

#### 1.3.2.2 Dependent parameters

- 1) Temperature of the HOHP.
- 2) Heat transfer of the HOHP.

#### 1.3.2.3 Control parameters

- 1) Total length of the pipe at the evaporator section was 850 mm.
- 2) Total length of the pipe at the condenser section was 850 mm.
- 3) Length of the adiabatic section was 50 mm.
- 4) Temperature of the water in the condenser section was 20°C.
- 5) Mass flow rate of the water at the inlet of the evaporator and the condenser sections was 0.25 kg/min.
- 6) Filling ratio was 80% with respect to the total volume of the HOHP.
- 7) Inclination angle was 90° from the horizontal.
- 8) Number of coils in the evaporator and the condenser sections was 5.
- 9) Diameter of coil was 50 mm.
- 10) Pitch was 10 mm.

### 1.3.3 Scope of heat exchanger

To prove that the HOHP heat exchanger can exchange a heat of 1000 W and that it has the conditions as follows:

- 1) Working fluid that provides the best heat transfer from the scope of the experiment in topic 1.3.2.
- 2) Temperature that provides the best heat transfer from the scope of the experiment in topic 1.3.2.
- 3) HOHP made from copper pipe that provides the best heat transfer from the scope of the experiment in topic 1.3.2.
- 4) Temperature of water in the condenser section was 20°C.

5) Mass flow rate of the water at the evaporator and the condenser sections was 0.25 kg/min.

6) Total length of the pipe at the evaporator section that provides the best heat transfer from the scope of the experiment in topic 1.3.2.

7) Total length of the pipe at the condenser section that provides the best heat transfer from the scope of the experiment in topic 1.3.2.

8) Adiabatic section was 50 mm.

9) Inclination angle was 90 degrees from the horizontal.

10) Heat exchanger has counter flow arrangement.

#### **1.4 Benefits of this study**

1.4.1 Mathematical model for the prediction the heat transfer of the HOHP.

1.4.2 Comparison of the results from the mathematical model and the experiments.

1.4.3 Design and creation of the heat exchanger.

1.4.4 Comparison of the performance of the heat exchanger from the model with the experiments.

## CHAPTER 2

### THEORY AND LITERATURE REVIEWS

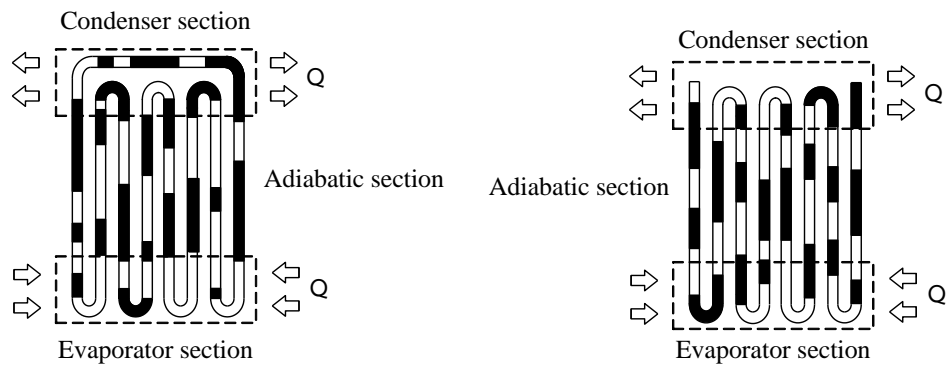

For the study of a mathematical model of a HOHP, the numerical method needs to know the basic information about the HOHP, which can be describe as follows:

1. Theory of oscillating heat pipe (OHP)
2. Theory of HOHP
3. Theory of mathematical model of HOHP
4. Numerical method
5. Theory of HOHP heat exchanger
6. Literature reviews

#### 2.1 Theory of oscillating heat pipe (OHP)

An OHP is heat transfer equipment that does not use external energy. The OHP consists of three sections: the evaporator section ( $L_e$ ), the adiabatic section ( $L_a$ ) and the condenser section ( $L_c$ ). The OHP can be operated by adding a working fluid to the capillary tube, for which, when the working fluid is in the saturated liquid state boiling occurs, and it is condensed into steam by the latent heat of vaporization and moves to the condenser section. The condenser section has a lower temperature, the steam condenses and moves to the other end of the pipe. Therefore, the working fluid steam can transfer the heat from one end of the pipe to the other end of the pipe, if the temperatures of the evaporator and the condenser sections are different. OHPs can be classified into four types: closed-end oscillating heat pipe (CEOHP), closed-loop oscillating heat pipe (CLOHP), closed-loop oscillating heat pipe with check valve (CLOHP/CV) and helical oscillating heat pipe (HOHP) [2], which are shown in figure 2.1.

(a) Closed-end oscillating heat pipe  
(CEOHP)

(b) Closed-loop oscillating heat pipe  
(CLOHP)

(c) Closed-loop oscillating heat pipe  
with check valve (CLOHP/CV)

(d) Helical oscillating heat pipe  
(HOHP) [25]

Figure 2.1 Oscillating heat pipes (OHP) [2]

The heat transfer characteristic of the OHP is the relationship of the actual heat transfer ( $Q$ ), the overall heat transfer ( $Z$ ) and the difference between the temperature of the heat source and the heat sink ( $\Delta T$ ). Which can be calculated by equation (2.1) [2].

$$Q = \frac{\Delta T}{Z} \quad (2.1)$$

The heat transfer of the OHP, also has the parameter control of the thermal resistance, which can be calculated by equation (2.2) [2].

$$Z = \frac{(T_{evap} - T_{cond})}{Q} \quad (2.2)$$

The calculation of the heat transfer of the OHP can be done by measuring the temperature of the cooling substance at the inlet and outlet of the condenser section, which can be calculated by equation (2.3) [2].

$$Q = \dot{m}c_p(T_{out} - T_{in}) \quad (2.3)$$

## 2.2 Theory of HOHP

The HOHP is a small pipe that has a high heat transfer coefficient. HOHPs are widely used in industry, such as in heat recovery systems, air conditioning and the food industry. The HOHP increases the heat transfer area more than the loop heat pipe, and it can be installed in a small area. The HOHP design has the evaporator and the condenser sections as pipes bent into a coil spring, and the adiabatic section is a straight pipe. A schematic of a HOHP is shown in figure 2.2. In which the length of the evaporator section is  $L_e$ , the length of the adiabatic section is  $L_a$ , the length of the condenser section is  $L_c$ , the radial of the coil is  $r_a$ , the radial of the pipe is  $a$  and the pitch is  $p_s$  [3].

Figure 2.2 Schematic of HOHP [3]

### 2.2.1 Geometry of HOHP

The geometry of the HOHP is shown in figure 2.3(a); the pitch  $p_s$  is increased by the number of coils in the equation  $2\pi p_s$  and it has important equations that consist of those for the curvature ( $\kappa$ ) and the torsion ( $\tau$ ). These can be seen in equation (2.4) and equation (2.5).

$$\kappa = \frac{r_a^2}{(r_a^2 + p_s^2)} \quad (2.4)$$

$$\tau = \frac{p_s^2}{(r_a^2 + p_s^2)} \quad (2.5)$$

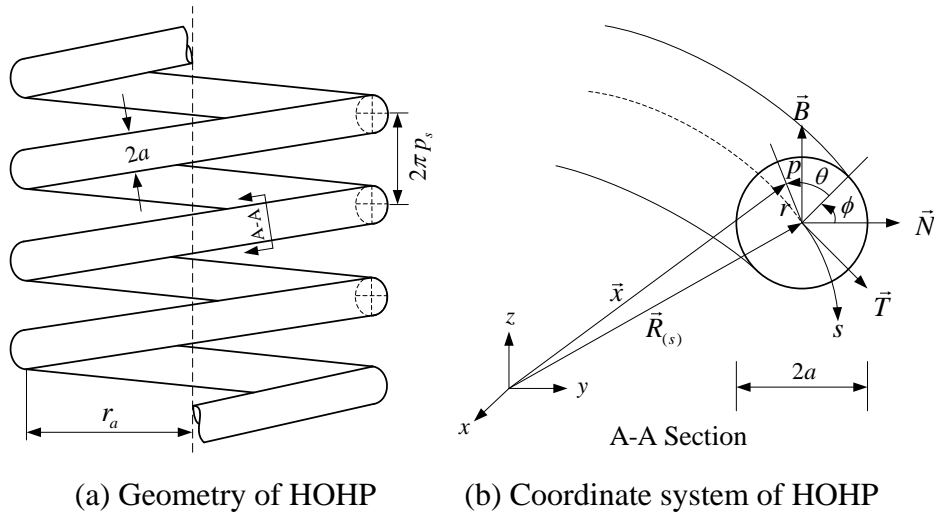

Figure 2.3 Geometry and coordinate system of HOHP [4]

### 2.2.2 Coordinate system of HOHP

The coordinate system of the HOHP can be considered as a master Cartesian coordinate system  $(x, y, z)$ . The coordinate system of the HOHP can be seen in figure 2.3(b), where  $s$  is the curvature direction,  $r$  is the radial direction and  $\theta$  is the angle direction. The vector in the coordinate system of the HOHP is  $\vec{R}_{(s)}$ , which can be calculate in equation (2.6).

$$\vec{R}_{(s)} = a \cos(s)\vec{i} + a \sin(s)\vec{j} + b(s)\vec{k} \quad (2.6)$$

where  $\vec{i}, \vec{j}$  and  $\vec{k}$  are the unit vectors and  $s$  is the vector in the curvature of the HOHP. The position  $x$  of the HOHP can be written in vector  $\vec{X}$  as can be calculate in equation (2.7).

$$\vec{X} = \vec{R}_{(s)} - r \sin(\theta - \tau s)\vec{N}_{(s)} + r \cos(\theta - \tau s)\vec{B}_{(s)} \quad (2.7)$$

The metric in the coordinate system of the HOHP can be shown in equation (2.8).

$$d\vec{x} \cdot d\vec{x} = (1 + \kappa r \sin(\theta - \tau s))^2 ds^2 + dr^2 + r^2 d\theta^2 \quad (2.8)$$

when  $ds, dr$  and  $d\theta$  are the variation in the rate in the axial, radial and angle directions, respectively. The unit matrix  $h_s$  can be calculated from equation (2.9).

$$h_s = 1 + \kappa r \sin(\theta - \tau s) \quad (2.9)$$

### 2.3 Theory of mathematical model of HOHP

When studying the details of the HOHP, it is very complex because the HOHP has more parameters in the analysis, in which the analysis of the HOHP will include the pipe wall and the vapor core of the HOHP. The pipe wall of the HOHP has the governing equation as the conduction equation. The vapor core in the HOHP has the governing equation as the continuity, the mass and the energy equations. These can be describe as follows:

#### 2.3.1 Conduction equation

The conduction equation at the pipe wall of the HOHP can be shown from the control volume in the coordinate system as in figure 2.4. The conduction rate along the HOHP is  $q_s$ .

Figure 2.4 Control volume on coordinate system of HOHP

From the control volume in figure 2.4, the energy conservation is:

$$\dot{E}_{in} + \dot{E}_g - \dot{E}_{out} = \dot{E}_{st} \quad (2.10)$$

where  $\dot{E}_{in}$  is the energy inflow,  $\dot{E}_{out}$  is the energy outflow,  $\dot{E}_g$  is the energy generation and  $\dot{E}_{st}$  is the energy storage.

### 2.3.2 Conservation of mass equation

Consider the fluid particle as shown in figure 2.5, the lengths of each side of the fluid particle are  $dr$ ,  $d\theta$  and  $ds$  according to the coordinates  $x$ ,  $y$  and  $z$  of the particle and the fluid will have the mass flux through the flow as can be seen in figure 2.5.

Figure 2.5 Mass flux through small area of fluid

The control volumes are the volume of the fluid particle and the conservation of mass equations, as shown in equation (2.11).

$$\frac{\partial}{\partial t} \int_{cv} \rho dV + \int_{cs} \rho \vec{V} \cdot d\vec{A} = 0 \quad (2.11)$$

where  $\rho$  is the density of mass,  $\forall$  is the volume of mass,  $\vec{V}$  is the velocity vector in the flow and  $\vec{A}$  is the vector of the cross section area of the small area.

### 2.3.3 Conservation of momentum equation

When considering the fluid particle as shown in figure 2.6, the control volumes are  $dr$ ,  $d\theta$  and  $ds$ , as can be shown by the following:

$$\vec{F} = \vec{F}_S + \vec{F}_B = \frac{\partial}{\partial t} \int_{cv} \vec{V} \rho d\forall + \int_{cs} \vec{V} \rho \vec{V} \cdot d\vec{A} \quad (2.12)$$

where  $\vec{F}_S$  is the surface tension force on the control volume and  $\vec{F}_B$  is the weight of the control volume.

Figure 2.6 Stress on surface of control volume

### 2.3.4 Conservation of energy equation

When considering the fluid particle, as shown in figure 2.7, the control volumes of the fluid particle are  $dr$ ,  $d\theta$  and  $ds$ . The differential equation of the energy can be created by the first thermodynamic law, therefore the energy equation can be calculated from equation (2.13).

$$\rho \frac{D}{Dt} \left( e + \frac{V^2}{2} \right) ds = \left[ \rho \bar{Q} - \frac{\partial q_s}{\partial s} \right] ds + \rho \vec{f} \cdot \vec{V} ds \quad (2.13)$$

where  $e$  is the internal energy,  $\frac{V^2}{2}$  is the kinetic energy of the mass,  $\vec{V}$  is the velocity of the flow,  $\bar{Q}$  is the heat flux occurring within the mass,  $\vec{f}$  is the force from the weight of the mass and  $q_s$  is the heat flux in the  $s$  direction.

Figure 2.7 Work on control volume

### 2.3.5 Heat transfer calculation of HOHP from model

The calculation of the heat transfer for the HOHP from the model can be defined as the overall heat transfer from the evaporator section to the condenser section, or due to the heat transfer between the pipe wall and the working fluid. The heat transfer from the state change of the working fluid can be calculated from equation (2.14) and the heat transfer at the surface can be calculated from equation (2.15) [2].

$$Q_v = \dot{m}_v h_{fg,i} \quad (2.14)$$

$$Q_{out} = \int_{i=1}^n \pi D h_c (T_{v,i} - T_{w,i}) dx \quad (2.15)$$

where  $Q_v$  is the heat transfer of the working fluid,  $\dot{m}_v$  is the mass flow rate of the working fluid,  $h_{fg}$  is the latent heat of the vaporization of the working fluid,  $Q_{out}$  is the heat transfer at the outlet of the condenser section,  $D$  is the diameter of the pipe,  $h$  is the convective heat transfer coefficient,  $T_v$  is the temperature of the working fluid in the pipe and  $T_w$  is the temperature of the heat pipe wall.

### 2.3.6 Heat transfer calculation of HOHP from experiment

The calculation of the heat transfer for the HOHP from the experiment can be done by the calorimeter method, which uses the measurement of the inlet and outlet temperatures of the water at the condenser section of the HOHP, when the values were calculated for the heat transfer using equation (2.16) and equation (2.17).

$$Q = \dot{m} c_p (T_{out} - T_{in}) \quad (2.16)$$

where  $Q$  is the heat transfer of the HOHP (W).

$\dot{m}$  is the mass flow rate (kg/s).

$c_p$  is the specific heat (J/kg °C).

$T_{in}$  is the inlet temperature at the condenser section (°C).

$T_{out}$  is the outlet temperature at the condenser section (°C).

## 2.4 Numerical method

The numerical method [5] used in the analysis of the mathematical model of the HOHP is the Crank-Nicolson method, which can be used to solve the heat equation as well and has high accuracy and few errors. The Crank-Nicolson method performs the calculation by estimating the term of the first time derivative of the variation with the time for the middle during of the period of the calculation as time  $n$  and  $n+1$ , which can be calculated from equation (2.17).

$$\frac{\partial T}{\partial t} = \frac{T_i^{n+1} - T_i^n}{\Delta t} \quad (2.17)$$

The first time derivative has variation with distance and can be calculated from equation (2.18).

$$\frac{\partial T}{\partial x} = \frac{1}{2} \left( \frac{T_{i+1}^{n+1} - T_{i-1}^{n+1}}{2\Delta x} + \frac{T_{i+1}^n - T_{i-1}^n}{2\Delta x} \right) \quad (2.18)$$

The second time derivative has variation with distance and can be calculated from equation (2.19).

$$\frac{\partial^2 T}{\partial x^2} = \frac{1}{2} \left( \frac{T_{i+1}^{n+1} - 2T_i^{n+1} + T_{i-1}^{n+1}}{\Delta x^2} + \frac{T_{i+1}^n - 2T_i^n + T_{i-1}^n}{\Delta x^2} \right) \quad (2.19)$$

The terms that do not vary with time and distance can be calculated from equation (2.20).

$$T = \frac{1}{2} (T_i^{n+1} - T_i^n) \quad (2.20)$$

## 2.5 Theory of HOHP heat exchanger

A heat exchanger is the application of several combined heat pipes for heat exchange from two types of fluid. The application of the heat pipe for heat exchange is called a heat pipe heat exchanger. The heat pipe heat exchanger is a closed system for the heat exchange from the hot fluid and the cool fluid, air or gas. Heat exchangers are designed to be used in hot systems and cold systems, such as the processes of electricity produced from gas or steam, refrigeration, cooling and in the food and chemical industries, etc. The heat exchanger has the principles of heat transfer from three processes that are heat conduction, heat convection and heat radiation. The design of a heat exchanger needs to consider the operating conditions above, as well as the money

invested, the performance, the size and the economic evaluation. We also must consider the materials used for the assembly, the corrosion resistance to chemicals and the physical properties of the heat, too [1].

For the analysis of the heat exchanger we must know the flow of the heat exchanger, the calculation of the number of tubes of the heat exchanger, the placement of the pipe in the heat exchanger, the overall heat transfer coefficient of the heat exchanger and the analysis and the calculation of the heat exchanger. Each of which are described as in the following:

### 2.5.1 Flow of heat exchanger

There are many types of heat exchanger and the heat pipe heat exchanger is a closed system, which has the hot fluid and the cool fluid within the heat exchanger for the heat exchange. The heat pipe heat exchanger can be classification by the two flow arrangements: the parallel flow and the counter flow [1]. In this study, we choose the counter flow due to it having the higher heat transfer and the efficiency in the exchange is better than the parallel flow. The counter flow is shown in figure 2.8.

Figure 2.8 Counter flow in heat exchanger [1]

### 2.5.2 Calculation for number of tubes in heat exchanger

The calculation of the number of tubes in the heat exchanger can be determined from equation (2.21).

$$N = \frac{Q}{Q_{Theory}} \quad (2.21)$$

where  $N$  is the number of tubes in the heat exchanger.

$Q$  is the actual heat transfer (W).

$Q_{Theory}$  is the heat transfer from the model (W).

### 2.5.3 Tube alignment in heat exchanger

The alignment of the tubes in the heat exchanger is very important in the heat exchange of the heat exchanger, in which the best alignment can help to give a higher heat transfer. The alignment of the tubes can be arranged in two ways, which are staggered or in-line [1]. In this study, we choose the staggered alignment because it has a higher heat transfer than the in-line alignment. The staggered alignment is shown in figure 2.9.

Figure 2.9 Staggered alignment [6]

Figure 2.9 shows the staggered alignment, which has the parameters in the analysis of the heat transfer of the heat exchanger as follows [6]:

$S_T$  is the transverse pitch.

$S_L$  is the longitudinal pitch.

$S_D$  is the diagonal pitch.

where  $S_D$  can be calculated from equation (2.22).

$$S_D = \left[ S_L^2 + \left( \frac{S_T}{2} \right)^2 \right]^{\frac{1}{2}} \quad (2.22)$$

The  $A_l$  group of tubes can be calculated from equation (2.23).

$$A_l = S_T L \quad (2.23)$$

The  $A_D$  group of tubes can be calculated from equation (2.24).

$$A_D = (S_D - D_o) L \quad (2.24)$$

The staggered alignment has the maximum velocity at the horizontal plane ( $A_l$ ) or the diagonal ( $A_D$ ), in which  $V_{\max}$  will occurred at  $A_D$  when

$2(S_D - D_o) < (S_T - D_o)$  or  $SD < \frac{S_T + D_o}{2}$  and  $V_{\max}$  can be calculated from equation

(2.25).

$$V_{\max} = \left[ \frac{S_T}{2(S_D - D_o)} \right] V \quad (2.25)$$

However, on the other hand, if  $V_{\max}$  occurred at  $A_l$  then  $V_{\max}$  can be calculated from equation (2.26).

$$V_{\max} = \left[ \frac{S_T}{S_T - D_o} \right] V \quad (2.26)$$

$V_{\max}$  is very important for the fluid flow, when it flows through a group of tubes. The Reynolds number can be calculated from  $V_{\max}$  in equation (2.27).

$$\text{Re}_D = \frac{\rho V_{\max} D_o}{\mu} \quad (2.27)$$

The heat transfer coefficient can be calculated from equation (2.28).

$$h = \frac{Nu_D K}{D_o} \quad (2.28)$$

The Nusselt number, obtained when using air to flow through the group of 10 tubes that has  $NL \geq 10$  and can be calculated from equation (2.29).

$$Nu_D = C_1 \text{Re}_{D,\max}^m, 2000 < \text{Re}_{D,\max}^m < 40000, \text{Pr} = 0.7 \quad (2.29)$$

$C_1$  and  $m$  can be seen from table 2.1.

When using air to flow through a group of tubes that is less than 10 tubes  $NL < 10$ , the Nusselt number can be calculated from equation (2.30).

$$Nu_D = C_1 C_2 \text{Re}_{D,\max}^m \quad (2.30)$$

$C_2$  and  $m$  can be seen from table 2.2.

When using other fluids to flow through the group of 10 tubes  $NL \geq 10$ , the Nusselt number can be calculated from equation (2.31).

$$Nu_D = 1.13C_1 Re_{D,\max}^m Pr^{1/3}, 2000 < Re_{D,\max}^m < 40000, Pr \geq 0.7 \quad (2.31)$$

When using other fluids to flow through a group of tubes that is less than 10 tubes  $NL < 10$ , the Nusselt number can be calculated from equation (2.32).

$$Nu_D = 1.13C_1C_2 Re_{D,\max}^m Pr^{1/3} \quad (2.32)$$

#### 2.5.4 Overall heat transfer coefficient of heat exchanger

In the analysis of the heat exchanger, we used the overall heat transfer ( $U$ ) as the value that indicates the heat transfer from fluid to fluid. The heat transfer between the two fluids has the temperature difference of  $\Delta T$ , which can be calculated from equation (2.33) [6].

$$Q = UA\Delta T \quad (2.33)$$

where  $U$  is the overall heat transfer coefficient for the heat exchanger, which can be calculated from equation (2.34).

$$U = \frac{1}{(1/h_e)} + \frac{1}{(1/h_c)} \quad (2.34)$$

Table 2.1 Edit value  $C_1$  when  $NL \geq 10$  [6].

### 2.5.5 Analysis and calculation of heat exchanger

The basis of the analysis and calculation of the heat exchanger is the calculation of the area in the heat exchange, and after that we can defined the shapes and the sizes of the heat exchanger depending on the usage. The location is an important factor in determining the appropriate position, the size and the area. The analysis requires various information, such as the flow rate of the fluid, the temperatures of the inlet and outlet fluids, the capability of the heat transfer, the quantity of heat in the

transfer and the property of the fluid, etc. The analysis and calculation of the heat exchanger has two methods, which are the log mean temperature difference method (LMTD) and the number of transfer unit method (NTU). In this study, will show the analysis from the NTU method, which can be described as follows:

The analysis by the NTU method has advantages over the LMTD, as we must know the size, type of the heat exchanger, the inlet and outlet temperatures and the flow rate. The NTU method can be calculated from equation (2.35) [6].

$$Q = \varepsilon Q_{\max} \quad (2.35)$$

where  $Q$  is the actual heat transfer (W).

$Q_{\max}$  is the maximum heat transfer (W).

$\varepsilon$  is the effectiveness of the heat exchanger.

The actual heat transfer can be calculated from equation (2.36).

$$Q = C_c (T_{c,o} - T_{c,i}) \quad (2.36)$$

where  $C_c$  is the  $\dot{m}c_p$  of the cooling fluid.

$T_{c,i}$  is the inlet temperature of the cooling fluid ( $^{\circ}\text{C}$ ).

$T_{c,o}$  is the outlet temperature of the cooling fluid ( $^{\circ}\text{C}$ ).

The maximum heat transfer can be calculated from equation (2.37).

$$Q_{\max} = C_{\min} (T_{h,i} - T_{c,i}) \quad (2.37)$$

where  $T_{h,i}$  is the inlet temperature of the hot fluid ( $^{\circ}\text{C}$ ).

$T_{h,o}$  is the outlet temperature of the hot fluid ( $^{\circ}\text{C}$ ).

The  $C_{\min}$  can be calculated from equation (2.38).

$$C_{\min} = (\dot{m}c_p)_{\min} \quad (2.38)$$

The velocity ( $V$ ) can be calculated from equation (2.39).

$$V = \frac{\dot{m}}{\rho A} \quad (2.39)$$

when  $C_{\min}$  is less than the  $\dot{m}c_p$  between the hot fluid and the  $\dot{m}c_p$  of the cool fluid, any value less, it is  $C_{\min}$ , and likewise when the value is more, it is  $C_{\max}$ . The value of  $\varepsilon$  is the ratio of  $C_{\min} / C_{\max}$  and will be analyzed by the NTU method from equation (2.40) [6].

$$NTU = \frac{UA}{C_{\min}} \quad (2.40)$$

The calculation of the effectiveness of the heat exchanger can be determined from equation (2.41) for the counter flow and when  $N = NTU = UA/C_{\min}$  and  $C = C_{\min} / C_{\max}$  [6].

$$\varepsilon = \frac{1 - \exp[-NTU(1-C)]}{1 - C \exp[-NTU(1-C)]} \quad (2.41)$$

## 2.6 Literature review

Sakulchangsattajai [2] improved and extend the mathematical physical model of Shafii et al. (2001), which is used to predict the behavior of the liquid and vapor within a CEOHP and CLOHP at the top heat mode, by increasing the adiabatic section and number of meandering turns. The model of the liquid and vapor behavior was formulated using the following assumptions: the internal flow was a single-phase flow,

the pressure loss at the bend turn was neglected, the liquid was incompressible and the vapor followed the ideal gas law. The principles and theories of the internal friction flow, basic governing equations and finite difference scheme were applied to evaluate the heat transfer rate. The computer program used in this research was the MATLAB program. It was found that the heat transfer of the CEOHP and CLOHP were predicted using the model with the adiabatic section and number of turns and compared with the experimental data of Rittidech et al. (2000) and Charoensawan et al. (2000), respectively. It was concluded that for both types of OHP the calculation results were fairly good when compared with the experimental evaluation. When the number of turns increased, the heat flux was nearly constant due to the symmetry within the heat pipe, as the heat transfer rate is increased. The operations of the CEOHP and CLOHP from the prediction were similar. The CLOHP with ethanol exhibited the highest heat flux, while R123 and water had less heat flux. The heat flux was proportional to the inner diameter of the tube and inversely proportional to the evaporator length.

Pipatpaiboon et al. [3] presented a new type of oscillating heat pipe (OHPs) that was the HOHP. The research aimed to study the effect of the working temperature on the heat transfer characteristics of the HOHP. The HOHP in the research was made from copper tube with an inside diameter of 4 mm. The total length of the HOHP was 3.75 m and consisted of the evaporator and condenser of equal lengths of 1.75 m and the length of the adiabatic was 0.25 m. Water was used as the working fluid at a filling ratio of 50% by total volume. The evaporator section was heated with an electric heater and the condenser section was cooled using an air flow when the air velocity was controlled at 1 m/s. The controlled temperatures at the adiabatic section (working temperature) were 50, 60 and 70°C respectively. The experimental inclination angles of 20, 40, 60, 80 and 90° from the horizontal axis were used. The results show that the working temperature increased the heat flux of the HOHP, and the maximum heat flux occurred at a working temperature of 70°C and inclination angle of 60° and it was 3065.08 W/m<sup>2</sup>. The HOHP works well at inclination angles between 60-90°

Germano [4] studied the effect of the torsion on a helical pipe. The Navier-Stokes equations for a steady incompressible viscous flow were explicitly written in this frame of reference. The result is that for curvatures and torsions of the same order and

for low Reynolds numbers, the curvature induces a flow with a first-order effect on the parameter  $\varepsilon = \kappa a$ , where  $\kappa$  is the curvature and  $a$  is the radius of the pipe.

Akbaridoust et al. [7] studied the laminar, steady state flow in helically coiled tubes at a constant wall temperature numerically and experimentally. In the experimental section, a heat exchanger was designed that was capable of providing a constant wall temperature for the coils with different curvatures and torsion ratios for the ease of assembly. In the numerical study, the three dimensional governing equations were solved by the finite difference method with a projection algorithm using the FORTRAN programming language. It was found that the heat transfer was observed for tubes with greater curvature ratios. The utilization of a base fluid in a helical tube with a greater curvature compared to the use of a nanofluid in straight tubes enhanced the heat transfer more effectively.

Boothaisong [8] studied a three-dimensional model to simulate the heat transfer rate on a heat pipe in a transient condition. This article presents the details of a calculation domain consisting of a wall, a wick and a vapor core. The governing equation was numerically simulated using the finite element method. The three dimensional model attempted to predict the transient temperature, the velocity and the heat transfer rate profiles. The values obtained from the model calculation were then compared with the results from the experiments. The experiment showed that the time required to attain a steady state was reasonably consistent with the model. The working fluid r134a was the quickest to reach the steady state and transferred the greatest amount of heat.

Jayakumar et al. [9] studied the CFD analysis of single-phase flows inside helically coiled tubes. It has been well established that the heat transfer in a helical coil is higher than that in a corresponding straight pipe. This study presented the variation of the local Nusselt number along the length and circumference at the wall of a helical pipe. CFD simulations are carried out for vertically oriented helical coils by varying the coil parameters, such as (i) pitch circle diameter, (ii) tube pitch and (iii) pipe diameter, and their influence on the heat transfer was studied. After establishing the influence of these parameters, correlations for the prediction of the Nusselt number were developed. A correlation to predict the local values of the Nusselt number as a function of the angular location of the point was also presented.

Litster et al. [10] studied a 3D numerical analysis of the flow and mass transfer in helical pipes. The interpretation of the flow patterns and their impact on mass transfer is shown to require a non-orthogonal pseudo-stream function based visualization. The strong coupling between the torsion and curvature effects and the resulting secondary flow regimes are well characterized by a parameter combining both the Dean ( $Dn$ ) and Germano numbers ( $Gn$ ). For membrane separation applications, helical modules combining high curvature with low torsion would alleviate the concentration polarization and yield an appreciable flux improvement.

Nobari and Malvandi [11] studied the compressible viscous flow in a helical annulus numerically. A second order finite difference method based on the projection algorithm was used to solve the governing equations. Considering the hydrodynamically fully developed flow, the effects of different physical parameters, such as aspect ratio, torsion, curvature and Reynolds number, on the flow field were investigated in detail. The numerical results obtained indicated that a decrease in the aspect ratio and torsion number lead to an increase in the friction factor at a given Dean number.

Saffari and Moosavi [12] investigated the turbulent single-phase and two-phase (air–water) bubbly fluid flows in a vertical helical coil with analysis using computational fluid dynamics (CFD). The effects of the pipe diameter, coil diameter, coil pitch, Reynolds number and void fraction on the pressure loss, friction coefficient and flow characteristics were investigated. The three-dimensional governing equations of the continuity, momentum and energy were solved using the finite volume method. The SIMPLE algorithm was employed to solve the velocity and pressure fields. The results show that the friction coefficient increases with an increase in the curvature, pipe diameter and coil pitch and decreases with an increase in the coil diameter and void fraction. For void fractions up to 0.1, the numerical results indicate that the friction coefficient increases with an increase in the pipe diameter while keeping the coil pitch and diameter constant and decreases with an increase in the coil diameter. Finally, with an increase in the Reynolds number, the friction coefficient decreases while the void fraction increases.

Sakulchangsattajai et al. [13] studied the heat transfer characteristics of a CEOHP and a CLOHP under normal operating conditions that were modeled using the explicit finite element method. The principles and theories of the internal friction flow,

basic governing equations and finite difference scheme were applied to evaluate the heat transfer rate. The predicted heat transfer rate, obtained from the model, was compared to the existing experimental data. The effects of the working fluid, evaporator length and inner diameter on the performance of a CEOHP and a CLOHP were also investigated.

Sriudom et al. [14] studied the effect of the evaporator temperature, pitch distance and working fluid on the internal flow pattern and the heat transfer characteristics of the helical oscillating heat pipe. A Pyrex tube with an inner diameter of 2.4 mm was used to study the flow pattern in the evaporator section. Water and R123 were used as working fluids. In the evaporator section, the water temperature was varied at 60, 75 and 90°C. In the condenser section, the air had a temperature of 25°C. From the results, it was found that there were four internal flow patterns (bubble flow, slug flow, annular flow and stratified wavy flow). The maximum heat fluxes were 2,132.6 and 1,773.4 W/m<sup>2</sup> for the working fluids of R123 and water, respectively.

## CHAPTER 3

### RESEARCH METHODOLOGY

This chapter sets out details of the research methodology of the HOHP mathematical model, it divided into three parts as follows:

1. Mathematical model and numerical solution.
2. Experimental evaluation.
3. HOHP application to a HOHP heat exchanger.

#### 3.1 Mathematical model and numerical solution

##### 3.1.1 Mathematical model

The mathematical model was established to check the accuracy of the program by comparing prediction with the experimental results using the following conditions:

- 1) Working fluids of water, ethanol and R11.
- 2) Temperatures at the evaporator section were 60, 70 and 80°C.
- 3) Inner diameters were 1.6, 1.8 and 2.0 mm and thickness was 0.5 mm.
- 4) Total length of the pipe at the evaporator section was 850 mm.
- 5) Total length of the pipe at the condenser section was 850 mm.
- 6) Length of the adiabatic section was 50 mm.
- 7) Temperature of the water in the condenser section was 20°C.
- 8) Inclination angle was 90° from the horizontal.
- 9) Number of coils in the evaporator and the condenser sections were 5.
- 10) Diameter of coil was 50 mm.
- 11) Pitch was 10 mm.

Assumptions used in model were as follows:

- 1) Initial temperature of the working fluid was 25°C.
- 2) Gravity does not effect on the HOHP.
- 3) The analysis assumed that the HOHP can be stretched in a straight

line.

- 4) The convective heat transfer coefficient at the evaporator and the condenser sections were constant.
- 5) The working fluid in the HOHP was an idea gas.
- 6) The pressure in the HOHP was constant.
- 7) The temperatures of the evaporator and the condenser sections were constant.
- 8) The mass flow rate of the working fluid in the HOHP was constant.

From the assumptions above we can create the model for the analysis of the HOHP, as can be seen in figure 3.1(b).

### 3.1.2 Numerical solution

The numerical solution uses the numerical method with the temperature of the pipe wall and the temperature of the fluid within the HOHP, which can be seen in figure 3.1. The finite difference method is used for the solution of the conduction equation of the pipe wall and the flow equation of the vapor in the HOHP. The finite difference method divides the area into numerous small grids that have precise values in the calculation. The numerical solution of the HOHP is:

#### 3.1.2.1 Condition in calculation

At the end of pipe ( $x = 0$  and  $x = L_e + L_a + L_c$ ):

$$w_y = 0 \quad (3.1)$$

At the evaporator section:

$$\frac{\partial T}{\partial x} = T_e \quad (3.2)$$

At the adiabatic section:

$$\frac{\partial T}{\partial x} = T_{initial} \quad (3.3)$$

At the condenser section:

$$\frac{\partial T}{\partial x} = T_c \quad (3.4)$$

(a) The HOHP

(b) Schematic of the HOHP used in the model

Figure 3.1 HOHP and schematic of HOHP used in analysis of model [21]

### 3.1.2.2 Solution of conduction equation

From the energy conservation in equation (2.10) in chapter 2, the energy inflow can be calculated from equation (3.5).

$$\dot{E}_{in} = q_s \quad (3.5)$$

where  $q_s$  is heat transfer rate in the  $s$  direction.

The energy outflow can be calculated from equation (3.6).

$$\dot{E}_{out} = -q_{s+ds} \quad (3.6)$$

when

$$q_{s+ds} = q_s + \frac{\partial q_s}{\partial s} ds \quad (3.7)$$

where  $q$  is heat transfer rate at  $s + ds$  in the  $s$  direction.

Inside equation (2.10) has the energy term of the energy generation, which can be calculated from equation (3.8).

$$\dot{E}_g = \dot{q} ds \quad (3.8)$$

where  $\dot{q}$  is the energy rate in the volume ( $W / m^3$ ).

A variation will occur in the quantity of the heat energy stored in the material at the control volume. If it is assumed that the material does not experience a state change, therefore the term of the energy storage can be calculated from equation (3.9).

$$\dot{E}_{st} = \rho c_p \frac{\partial T}{\partial t} ds \quad (3.9)$$

where  $\rho c_p \frac{\partial T}{\partial t}$  is the rate of the heat energy that is changed in an appropriate time per volume.

Substituting equations (3.5), (3.6), (3.8) and (3.9) into equation (2.10) in chapter 2, we obtain the energy conservation as:

$$q_s + \dot{q}ds - q_{s+ds} = \rho c_p \frac{\partial T}{\partial t} ds \quad (3.10)$$

Substituting equation (3.7) into equation (3.10), we obtain:

$$-\frac{\partial q_s}{\partial s} ds + \dot{q}ds = \rho c_p \frac{\partial T}{\partial t} ds \quad (3.11)$$

The conduction rate can be considered by Fourier's Law in equation (3.12).

$$q = -kA \Delta T \quad (3.12)$$

where  $q$  is the heat transfer rate,  $k$  is the thermal conductivity,  $A$  is the area for the heat transfer and  $\Delta T$  is the difference in the temperature before and after the received heat, we obtain:

$$q_s = -k \frac{\partial T}{\partial s} \quad (3.13)$$

Substituting equation (3.13) into equation (3.11), we obtain:

$$-\frac{\partial}{\partial s} \left( -k \frac{\partial T}{\partial s} \right) ds + \dot{q}ds = \rho c_p \frac{\partial T}{\partial t} ds \quad (3.14)$$

Using  $ds$  to divide every term in equation (3.14) and rearranging the equation, we obtain the conduction equation of the HOHP in the 1-D transient as:

$$\rho_w c_{p,w} \frac{\partial T}{\partial t} = \frac{\partial}{\partial s} \left( k_w \frac{\partial T}{\partial s} \right) + \dot{q} \quad (3.15)$$

### 3.1.2.3 Solution of conservation of mass equation

From the conservation of mass equation in equation (2.11) in chapter 2, the first term is a variation in the rate of the mass in the control volume and when used with fluid particles can be obtain as:

$$\frac{\partial}{\partial t} (\rho ds) \quad (3.16)$$

The second term in equation (2.11) in chapter 2 is the variation in the rate of mass flow through the surface of the control volume, due to the density functions of distance and time, therefore the mass flow rate is:

In axial direction  $s$  
$$(\rho w|_{s+ds} - \rho w|_s) = \left( \rho w + \frac{\partial(\rho w)}{\partial s} ds \right) \quad (3.17)$$

Substitution equation (3.16) and (3.17) into equation (2.11) in chapter 2, we obtain:

$$\frac{\partial}{\partial t} (\rho ds) + \left( \rho w + \frac{\partial \rho w}{\partial s} ds \right) = 0 \quad (3.18)$$

Dividing equation (3.18) by  $ds$ , we obtain the continuity equation of the HOHP [1]:

$$\frac{\partial rw}{\partial s} = 0 \quad (3.19)$$

### 3.1.2.4 Solution of conservation of momentum equation

From the conservation of momentum equation in equation (2.12) in chapter 2, when using  $ds$  to divide the momentum equation and taking the limit of volume  $ds$  into zero, to limit both equations, we obtain:

$$\lim_{ds \rightarrow 0} \frac{\vec{F}_S}{ds} + \lim_{ds \rightarrow 0} \frac{\vec{F}_B}{ds} = \lim_{ds \rightarrow 0} \frac{\frac{\partial}{\partial t} \int_{cv} \vec{V} \rho dV}{ds} + \lim_{ds \rightarrow 0} \frac{\int_{cs} \vec{V} \rho \vec{V} \cdot d\vec{A}}{ds} \quad (3.20)$$

For the two terms on the left hand side of equation (3.20), which are the force at the surface and the force per volume on the surface of the fluid particle, the details are shown in figure 2.6 in chapter 2, and can be written as the force at the surface and the force of the mass in the  $S$  direction as the following:

$$\vec{F}_S + \vec{F}_B = \left( \sigma_{ss} \Big|_{s+ds} - \sigma_{ss} \Big|_s \right) + \left( \tau_{ss} \Big|_{s+ds} - \tau_{ss} \Big|_s \right) \quad (3.21)$$

When using the force in the  $S$  direction and substituting in equation (3.21), we obtain:

$$\lim_{ds \rightarrow 0} \frac{\vec{F}_S}{ds} + \lim_{ds \rightarrow 0} \frac{\vec{F}_B}{ds} = \lim_{ds \rightarrow 0} \frac{\left( \sigma_{ss} \Big|_{s+ds} - \sigma_{ss} \Big|_s \right)}{ds} + \lim_{ds \rightarrow 0} \frac{\left( \tau_{ss} \Big|_{s+ds} - \tau_{ss} \Big|_s \right)}{ds} \quad (3.22)$$

Equation (3.22) can be written as:

$$\lim_{ds \rightarrow 0} \frac{\vec{F}_S}{ds} + \lim_{ds \rightarrow 0} \frac{\vec{F}_B}{ds} = \frac{\partial \sigma_s}{\partial s} + \frac{\partial \tau_s}{\partial s} \quad (3.23)$$

For the first term on the right hand side in equation (3.20), its variation rate of the momentum within the control volume per unit of volume can be calculated from equation (3.24).

$$\lim_{ds \rightarrow 0} \frac{\frac{\partial}{\partial t} \int_{cv} \vec{V} \rho dV}{ds} = \lim_{ds \rightarrow 0} \frac{\partial}{\partial t} \left( \frac{\rho \vec{V} ds}{ds} \right) = \frac{\partial}{\partial t} (\rho \vec{V}) = \vec{V} \frac{\partial \rho}{\partial t} + \rho \frac{\partial \vec{V}}{\partial t} \quad (3.24)$$

The second term on the right hand side in equation (3.20) is the variation of the flow of the momentum through the surface of the control volume per unit of volume, which can be calculated from equation (3.25).

$$\lim_{ds \rightarrow 0} \frac{\int \vec{V} \rho \vec{V} \cdot d\vec{A}}{ds} = \lim_{ds \rightarrow 0} \frac{(\rho \vec{V} w|_{s+ds} - \rho \vec{V} w|_s)}{ds} \quad (3.25)$$

Equation (3.25) can be written as:

$$\lim_{ds \rightarrow 0} \frac{\int \vec{V} \rho \vec{V} \cdot d\vec{A}}{ds} = \lim_{ds \rightarrow 0} \frac{(\rho \vec{V} w|_{s+ds} - \rho \vec{V} w|_s)}{ds} = \frac{\partial}{\partial s} (\rho \vec{V} w) \quad (3.26)$$

Re arranging equation (3.26), we obtain:

$$\lim_{ds \rightarrow 0} \frac{\int \vec{V} \rho \vec{V} \cdot d\vec{A}}{ds} = \vec{V} \left[ \frac{\partial}{\partial s} (\rho w) \right] + \rho \left[ w \frac{\partial \vec{V}}{\partial s} \right] \quad (3.27)$$

From the continuity equation in equation (3.19).

$$\frac{\partial}{\partial s} (\rho w) = 0$$

Therefore, equation (3.27) can be re written as:

$$\lim_{ds \rightarrow 0} \frac{\int \vec{V} \rho \vec{V} \cdot d\vec{A}}{ds} = -\vec{V} \left[ \frac{\partial \rho}{\partial t} \right] + \rho \left[ w \frac{\partial \vec{V}}{\partial s} \right] \quad (3.28)$$

Substituting equations (3.23), (3.24) and (3.28) into equation (3.20), we obtain:

$$\rho \left( \frac{\partial w}{\partial t} + w \frac{\partial w}{\partial s} \right) = \frac{\partial \sigma_s}{\partial s} + \frac{\partial \tau_s}{\partial s} \quad (3.29)$$

The momentum conservation in equation (3.29) can be written as the momentum equation of the flow of the HOHP in the 1-D transient as [1]:

$$\frac{\partial w}{\partial t} + \frac{1}{h_s} \left( \frac{\partial w}{\partial s} \right) + \frac{\kappa \sin(\theta - \tau s)}{h_s} w + \frac{\kappa \cos(\theta - \tau s)}{h_s} w = -\frac{1}{h_s} \frac{\partial p}{\partial s} + \frac{1}{\text{Re}} \left[ \frac{1}{h_s} \frac{\partial}{\partial s} \left( \frac{1}{r h_s} \frac{\partial r w}{\partial s} \right) \right] \quad (3.30)$$

### 3.1.2.5 Solution of conservation of energy equation

From the conservation of energy equation in equation (2.13) in chapter 2, multiplying by the velocity of flow, it will become rate of work as:

$$\rho \vec{f} \cdot \vec{V} ds \quad (3.31)$$

From figure 2.7 in chapter 2, the rate of work occurring in the  $s$  direction can be calculated from equation (3.32).

$$\left[ -\frac{\partial (wp)}{\partial s} + \frac{\partial (w\sigma_{ss})}{\partial s} + \frac{\partial (w\tau_{ss})}{\partial s} \right] ds + \rho \vec{f} \cdot \vec{v} ds \quad (3.32)$$

The heat flux occurring from the mass can be calculated from equation (3.33).

$$\rho \bar{Q} ds \quad (3.33)$$

The total heat flux from the heat transfer in the  $s$  direction can be calculated from equation (3.34).

$$\left[ q_s - \left( q_s + \frac{\partial q_s}{\partial s} \right) \right] ds \quad (3.34)$$

Therefore, the total heat flux on the mass can be calculated from equation (3.35).

$$\left[ \rho \bar{Q} - \frac{\partial q_s}{\partial s} \right] ds \quad (3.35)$$

From Fourier's Law, the heat flux  $q_s$  variation on the slope of the temperature can be seen in equation (3.36).

$$q_s = -k \frac{\partial T}{\partial s} \quad (3.36)$$

Substituting equation (3.35) into equation (3.36), we can calculate the total heat flux from equation (3.37).

$$\left[ \rho \bar{Q} + \frac{\partial}{\partial s} \left( k \frac{\partial T}{\partial s} \right) \right] ds \quad (3.37)$$

Substituting equation (3.37) into the conservation of energy equation in equation (2.13) in chapter 2, we obtain the energy equation of the HOHP as:

$$\rho \frac{D}{Dt} \left( e + \frac{V^2}{2} \right) ds = \left[ \rho \bar{Q} + \frac{\partial}{\partial s} \left( k \frac{\partial T}{\partial s} \right) \right] ds + \rho \vec{f} \cdot \vec{V} ds \quad (3.38)$$

The equation (3.38) is in the form of absolute derivatives, which can be changed into simple derivatives for use with the conduction, the continuity and the momentum equations. The energy equation of the flow of the HOHP in the 1-D transient can be calculated from equation (3.39) [1].

$$\frac{\partial T}{\partial t} + \frac{w}{h_s} \frac{\partial T}{\partial s} = \frac{1}{\text{Re Pr } h_s r} \frac{\partial}{\partial s} \left( \frac{r}{h_s} \frac{\partial T}{\partial s} \right) \quad (3.39)$$

### 3.1.2.6 Solution of heat transfer equation of HOHP

From the heat transfer equations in equations (2.14) and (2.15) in chapter 2, they can be changed to the finite difference method form, as is shown in equations (3.40) and (3.41).

$$Q_v^{new} = \dot{m}_v h_{fg,i} \quad (3.40)$$

$$Q_{out}^{new} = \pi D h_c (T_{v,i} - T_{w,i}) \quad (3.41)$$

### 3.1.2.7 Flow chart of program

The numerical procedure is illustrated in figure 3.2. The calculation procedure of the simulation program is as follows:

1) Input the lengths of the evaporator section ( $L_e$ ), the adiabatic section ( $L_e$ ) and the condenser section ( $L_c$ ); the outer diameter ( $D_o$ ) and inner diameter ( $D_i$ ); the temperatures of the evaporator ( $T_e$ ) and the condenser sections ( $T_c$ ); and the working fluid within the HOHP.

2) Start calculation at the first point  $i = 1$ .

3) Input the initial temperature of the pipe wall of the HOHP ( $T_{w,ini}$ ), the thermal conductivity of the pipe wall ( $k_w$ ), the density of the pipe wall ( $\rho_w$ ), the specific heat ( $C_{p,w}$ ) and the grid size in the  $s$  direction ( $\Delta s$ ), and then calculate the temperature of the pipe wall in the conduction equation.

4) Input the initial velocity of the vapor in the HOHP ( $w_{ini}$ ), the grid size in the  $s$  direction ( $\Delta s$ ), the scale factor ( $h_s$ ), the pressure ( $p$ ), the Reynolds number ( $Re$ ), the curvature ratio ( $\kappa$ ), the inclination angle ( $\theta$ ) and the density of the working fluid ( $\rho$ ), and then calculate the velocity of the vapor in the continuity and momentum equations.

5) Input the initial temperature of the vapor in the HOHP ( $T_{v,ini}$ ), the velocity of the vapor ( $w$ ), the grid size in the  $s$  direction ( $\Delta s$ ), the scale factor ( $h_s$ ), the Reynolds number ( $Re$ ), the Prandtl number ( $Pr$ ) and the radial of the HOHP ( $r$ ), and then calculate the temperature of the vapor in the energy equation.

6) Receive the data of the temperature: the temperature of the pipe wall ( $T_w$ ) and the temperature of the vapor ( $T_v$ ) from the conduction and energy equations.

7) Input the inner diameter of the HOHP ( $D_i$ ) and the convection heat transfer coefficient ( $h$ ) and then calculate the heat transfer of the HOHP in the heat transfer equation.

8) Calculate the next point  $i = i + 1$ , and check the last point in the calculation as to whether this is equal to the maximum point or not.

9) If the last point is equal to the maximum point, stop the calculation, or if it is not equal to the maximum point, return to the first step.

When the calculation is finished, the working fluid should be changed from water into ethanol and R11.

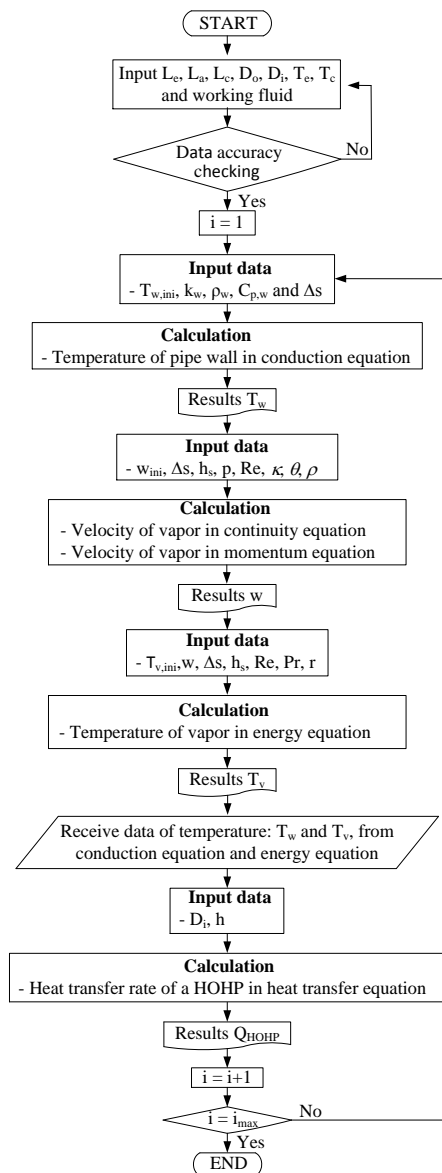

Figure 3.2 Flow chart for calculation of HOHP

## 3.2 Experimental evaluation

### 3.2.1 Variables in experiment

#### 3.2.1.1 Dependent variables

- 1) Working fluids were water, ethanol and R11.
- 2) Temperatures of the evaporator section were 60, 70 and 80°C.
- 3) HOHP made from copper pipe with inner diameters of 1.6, 1.8 and 2.0 mm and thickness of 0.5 mm.

### 3.2.1.2 Dependent parameters

- 1) Temperature of the HOHP.
- 2) Heat transfer of the HOHP.

### 3.2.1.3 Control parameters

- 1) Total length of the pipe at the evaporator section was 850 mm.
- 2) Total length of the pipe at the condenser section was 850 mm.
- 3) Length of the adiabatic section was 50 mm.
- 4) Temperature of the water in the condenser section was 20°C.
- 5) Mass flow rate of the water at the evaporator and the condenser sections was 0.25 kg/min.
- 6) Filling ratio was 80% with respect to the total volume of the HOHP.
- 7) Inclination angle was 90° to the horizontal.
- 8) Number of coils in the evaporator and the condenser sections were 5.
- 9) Diameter of coil was 50 mm.
- 10) Pitch was 10 mm.

## 3.2.2 HOHP in experimental evaluation

3.2.2.1 The HOHP was made from copper pipe. The HOHP had three section: the evaporator, the adiabatic and the condenser sections, and is shown in figure 3.3.

Figure 3.3 HOHP

### 3.2.3 Equipment and measurements used during experiment

#### 3.2.3.1 Data logger

The data logger measured the temperature at any point and recorded the data. The data logger is a Yokogawa DX200 with  $\pm 0.1^{\circ}\text{C}$  accuracy, 20 channel input and a  $-200^{\circ}\text{C}$  to  $1100^{\circ}\text{C}$  measurement temperature range, as shown in figure 3.4.

Figure 3.4 Data logger

#### 3.2.3.2 Thermocouples

The thermocouples used in the experimental were type K (OMEGA with  $\pm 0.1^{\circ}\text{C}$  accuracy); the range of the operating temperature was between  $-100$  and  $1300^{\circ}\text{C}$ , as shown in figure 3.5.

Figure 3.5 Thermocouples

### 3.2.3.3 Working fluid filling set

The working fluid filling set consisted of four valves: a burette or pipette was connected to valve A for filling the working fluid, valve B was connected to a vacuum pump, valve C was connected to the heat pipe or tube and valve D was connected to a pressure gauge for measuring the pressure in the tube, as shown in figure 3.6.

Figure 3.6 Working fluid filling set

### 3.2.3.4 Hot water bath

A hot water bath was used to control the temperature of the water and to heat it to set the temperature. This study used a TECHNE TE-10D with an operating range of  $-40$  to  $120^{\circ}\text{C}$  and  $\pm 0.1^{\circ}\text{C}$  accuracy, as shown in figure 3.7.

Figure 3.7 Hot bath

### 3.2.3.5 Cold water bath

The cold water bath was used to control the temperature and cool down the water to the set-up temperature. This study used an six liters EYELA CA -1111 with an operating temperature range of  $-20$  to  $30^{\circ}\text{C}$  and  $\pm 2^{\circ}\text{C}$  accuracy, as shown in figure 3.8.

Figure 3.8 Cool bath

### 3.2.3.6 Flow meter

The flow meter was used for measuring and controlling the flow rate of the water into the condenser and evaporator sections. This study used a PLATON PTF2 ASS-C with a flow rate of 0.2-1.5 liter/min. A floating rotameter was applied, as shown in figure 3.9.

Figure 3.9 Flow meter

### 3.2.3.7 Vacuum pump

A vacuum pump was used with the HOHP to create a vacuum before filling the working fluid shown in figure 3.10.

Figure 3.10 Vacuum pump

### 3.2.4 Experimental setup

The experimental setup of the HOHP is shown in figure 3.11, and a photograph of the experimental setup is shown in figure 3.12.

Figure 3.11 Schematic diagram of experimental setup of HOHP

Figure 3.12 Experimental setup of HOHP

### 3.2.5 Experimental procedure

3.2.5.1 The HOHP was made from copper pipe with an inner diameter determined from the scope of the experiment.

3.2.5.2 Fill the working fluid into the HOHP using the working fluid filling set as shown in figure 3.6, for which the procedure is as follows:

1) Close valves A, B and C, then join the HOHP into the working fluid set.

2) Open the vacuum pump and open valves A, B, D, and C for suction of the air out of the HOHP. When the HOHP has a vacuum, which can be seen from the pressure gauge, close valves A, B and D.

3) Fill the working fluid into the glass tube, then open valve C for the working fluid to flow into the filling working fluid set, and then open valve B and the working fluid will be able to flow to the HOHP.

4) When the working fluid has flown into the HOHP, then close valve B and close the end of the pipe by welding it. We have the HOHP for the experiments.

3.2.5.3 Set up the HOHP with the experimental platform, which can be seen in figure 3.13.

3.2.5.4 Set the hot water bath for boiling the water to the temperature of 60°C and open the pump that will pump the hot water to the evaporator section of the HOHP. At the condenser section, set the cold water bath for the cool water to the temperature of 20°C and open the pump that will pump the cooling water to the condenser section of the HOHP.

3.2.5.5 Set the flow meter to 0.25 kg/min for the water at the inlets of the evaporator and the condenser sections.

3.2.5.6 Open the data logger to save the pipe wall temperature at the evaporator, the adiabatic and the condenser sections and the inlet and outlet temperatures of the condenser section.

3.2.5.7 Perform the experimental from the first step to the last step, for which the working fluids, the temperatures of the evaporator section and the inner diameters are as shown in the scope of the experiment.

Figure 3.13 Filling working fluid procedure

### 3.2.6 Data analysis

The heat transfer of the HOHP can be calculated from equation (3.42).

$$Q = \dot{m} c_p (T_{out} - T_{in}) \quad (3.42)$$

where  $Q$  is the heat transfer of the HOHP (W).

$\dot{m}$  is the mass flow rate of the cooling water (kg/s).

$c_p$  is the specific heat of the cooling water (J/kg°C).

$T_{in}$  is the inlet temperature of the cooling water at the condenser (°C).

$T_{out}$  is the outlet temperature of the cooling water at the condenser (°C).

### 3.3 HOHP application to a HOHP heat exchanger

In the application of the heat exchanger, we want the heat exchange from the heat exchanger to be 1000 W, which has the details as in the following:

#### 3.3.1 Scope of HOHP heat exchanger

3.3.1.1 Working fluid that provided the best heat transfer from the scope of the experiment in topic 1.3.2 in chapter 1.

3.3.1.2 Temperature that provided the best heat transfer from the scope of the experiment in topic 1.3.2 in chapter 1.

3.3.1.3 HOHP made from copper pipe that provided the best heat transfer from the scope of the experiment in topic 1.3.2 in chapter 1.

3.3.1.4 Temperature of the water in the condenser section was 20°C.

3.3.1.5 Mass flow rates of the water at the evaporator and the condenser sections were 0.25 kg/min.

3.3.1.6 Total length of the pipe at the evaporator section that provided the best heat transfer from the scope of the experiment in topic 1.3.2 in chapter 1.

3.3.1.7 Total length of the pipe at the condenser section that provided the best heat transfer from the scope of the experiment in topic 1.3.2 in chapter 1.

3.3.1.8 Length of the adiabatic section was 50 mm.

3.3.1.9 Inclination angle was 90° from the horizontal.

3.3.1.10 Heat exchanger had counter flow arrangement.

Figure 3.14 Schematic diagram of experimental setup of HOHP heat exchanger

Figure 3.15 Experimental setup of HOHP heat exchanger

### 3.3.2 Experimental procedure of heat exchanger

3.3.2.1 Create the heat exchanger from the HOHP with the number of tubes as calculated by the model and with the inner diameter that performs the best heat transfer.

3.3.2.2 Filling of the working fluid that has best heat transfer into the HOHP, for which the procedure will be the same as with filling the working fluid of the HOHP.

3.3.2.3 Setup the heat exchanger with the experimental platform, which is shown in figure 3.14 and figure 3.15.

3.3.2.4 Open the hot water bath for the boiling water to the temperature has the highest heat transfer, and open the pump that pumps the hot water to the evaporator section of the heat exchanger. At the condenser section, open the cold water bath for cooling the water to the temperature of 20°C, and open the pump that pumps the cooling water to the condenser section of the heat exchanger.

3.3.2.5 Set the flow meter to 0.25 kg/min for the water at the inlets of the evaporator and the condenser sections.

3.3.2.6 Open the data logger to save the temperatures at the inlet and outlet of the condenser section.

### 3.3.3 Data analysis of heat exchanger

The heat transfer of the heat exchanger can be calculated:

$$Q = \varepsilon Q_{\max} \quad (3.43)$$

where  $Q$  is the actual heat transfer (W).

$Q_{\max}$  is the maximum heat transfer (W).

$\varepsilon$  is the effectiveness of the heat exchanger.

## CHAPTER 4

### RESULTS AND DISCUSSION

This chapter describes the results and discussions about the temperature and the heat transfer of the HOHP when studying the mathematical model under the transient condition. It is divided into three parts as follows:

1. Results from mathematical model.
2. Results from experimental evaluation.
3. Comparison of results from model and experiment.

#### 4.1 Results from mathematical model

##### 4.1.1 Temperature at pipe wall of HOHP from model

Figure 4.1 shows the temperature profiles at the pipe wall of the HOHP at the evaporator, the adiabatic and the condenser sections from the numerical model with the outer wall temperatures at the evaporator section of 60, 70 and 80°C, and water as the working fluid. The transient temperature profiles were plotted as functions of time. It was found that the transient temperature profiles in the evaporator section increased from the initial temperature at the outer pipe wall (25°C) to the temperatures that were input at the evaporator section (60, 70 and 80°C). Since the material of the pipe wall was copper, thermal conduction was induced from the outer wall of the pipe to the inner wall of the pipe. In the adiabatic section, heat was induced by thermal conduction from the evaporator section. The temperature of the adiabatic section increased until it reached a steady state, at which it was close to the working temperatures (the average value of the temperatures between the evaporator and the condenser sections). However, the transient temperature profiles in the condenser section decreased because the initial temperature of the outer pipe wall (25°C) was more than the temperature of the condenser section (20°C). The times required to reach the steady state temperature at the end of the runs from the numerical model were about 1300, 1600 and 2000 s for the temperatures at the evaporator section of 60, 70 and 80°C, respectively. As seen from figure 4.1, the temperature at the evaporator section increased, and the time required to

reach the steady state temperature was increased because the temperature was dependent on the time.

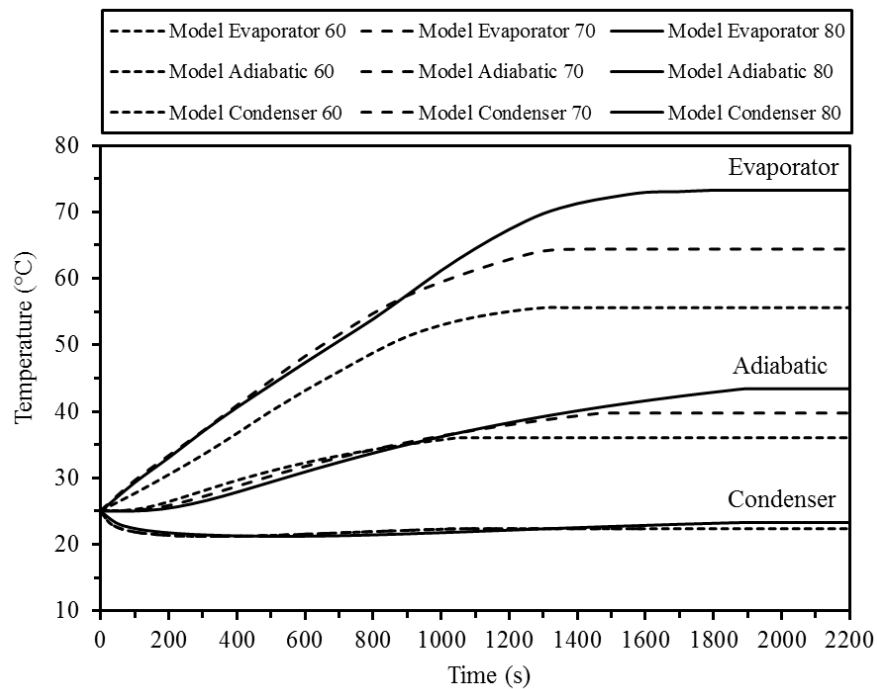

Figure 4.1 Temperature profiles at pipe wall of HOHP from model at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of water

Figure 4.2 shows the temperature profiles at the pipe wall of the HOHP at the evaporator, the adiabatic and the condenser sections from the numerical model with the outer wall temperatures at the evaporator section of  $60, 70$  and  $80^\circ\text{C}$ , and ethanol as the working fluid. The transient temperature profiles were plotted as functions of time. It was found that the transient temperature profiles in the evaporator section increased from the initial temperature at the outer pipe wall ( $25^\circ\text{C}$ ) to the temperatures that were input at the evaporator section ( $60, 70$  and  $80^\circ\text{C}$ ). Since the material of the pipe wall was copper, thermal conduction was then induced from the outer wall of the pipe to the inner wall of the pipe. In the adiabatic section, heat was induced by thermal conduction from the evaporator section. The temperature of the adiabatic section increased until it reached a steady state, in which it was close to the working temperatures (the average

value of the temperatures between the evaporator and the condenser sections). However, the transient temperature profiles in the condenser section decreased because the initial temperature of the outer pipe wall ( $25^{\circ}\text{C}$ ) was more than the temperature of the condenser section ( $20^{\circ}\text{C}$ ). The times required to reach the steady state temperature at the end of the runs from the numerical model were about 1200, 1500 and 1900 s for the temperatures at the evaporator section of 60, 70 and  $80^{\circ}\text{C}$ , respectively. As seen from figure 4.2, the temperature at the evaporator section increased, and the time required to reach the steady state temperature was increased because the temperature was dependent on the time.

Figure 4.2 Temperature profiles at pipe wall of HOHP from model at  $T_e = 60, 70$  and  $80^{\circ}\text{C}$  with working fluid of ethanol

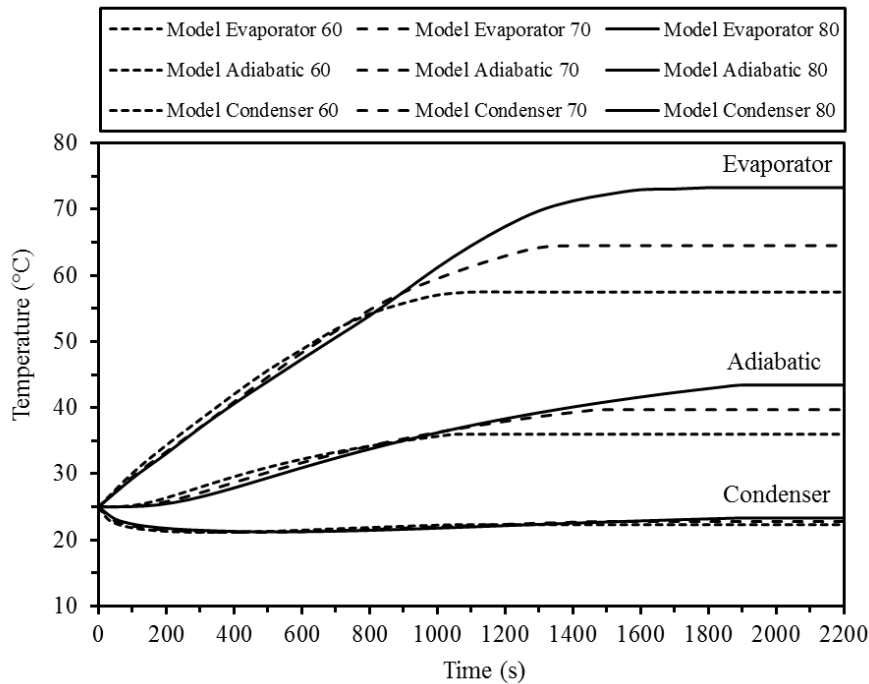

Figure 4.3 Temperature profiles at pipe wall of HOHP from model at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of R11

Figure 4.3 shows the temperature profiles at the pipe wall of the HOHP at the evaporator, the adiabatic and the condenser sections from the numerical model with the outer wall temperatures at the evaporator section of  $60, 70$  and  $80^\circ\text{C}$ , and R11 as the working fluid. The transient temperature profiles were plotted as functions of time. It was found that the transient temperature profiles in the evaporator section increased from the initial temperature at the outer pipe wall ( $25^\circ\text{C}$ ) to the temperatures that were input at the evaporator section ( $60, 70$  and  $80^\circ\text{C}$ ). Since the material of the pipe wall was copper, thermal conduction was then induced from the outer wall of the pipe to the inner wall of the pipe. In the adiabatic section, heat was induced by thermal conduction from the evaporator section. The temperature of the adiabatic section increased until it reached a steady state, at which it was close to the working temperatures (the average value of the temperatures between the evaporator and the condenser sections). However, the transient temperature profiles in the condenser section decreased because the initial temperature of the outer pipe wall ( $25^\circ\text{C}$ ) was more than the temperature of the condenser section ( $20^\circ\text{C}$ ). The times required to reach the steady state temperature at the

end of the runs from the numerical model were about 1100, 1400 and 1800 s for the temperatures at the evaporator section of 60, 70 and 80°C, respectively. As seen from figure 4.3, the temperature at the evaporator section increased, and the time required to reach the steady state temperature was increased because the temperature was dependent on the time.

It can be concluded that the times required to reach the steady state temperature at the end of the runs from the numerical model of the HOHP with the working fluid of R11 required times that were less than the working fluids of ethanol and water.

#### **4.1.2 Heat transfer of HOHP from model**

Figure 4.4 shows the heat transfer profiles from the numerical model under the transient condition of the HOHP with the outer wall temperatures at the evaporator section of 60, 70 and 80°C, and water as the working fluid. It was found that the times to start-up for the heat transfer of the HOHP from the numerical model were about 700, 800 and 900 s for the temperatures at the evaporator section of 60, 70 and 80°C, respectively. Moreover, this figure also shows the times required to reach the steady state heat transfer from the numerical model for the outer wall temperatures of 60, 70 and 80°C, for which the times required to reach the steady heat transfer were about 2000, 2200 and 2400 s, respectively. The temperature at the evaporator section of 60°C gave a time to reach the steady state heat transfer that was less than the temperatures at the evaporator section of 70 and 80 °C. The temperature for the evaporator section of 80°C had a higher heat transfer than the temperatures for the evaporator section of 70 and 60°C. When the temperature of the evaporator section was 80°C the heat transferred to the HOHP was more than the temperatures at the evaporator section of 70 and 60°C. As can be seen from figure 4.4, the time required to reach the steady state heat transfer and the heat transfer of the HOHP depend on the outer wall temperatures at the evaporator section of the HOHP.

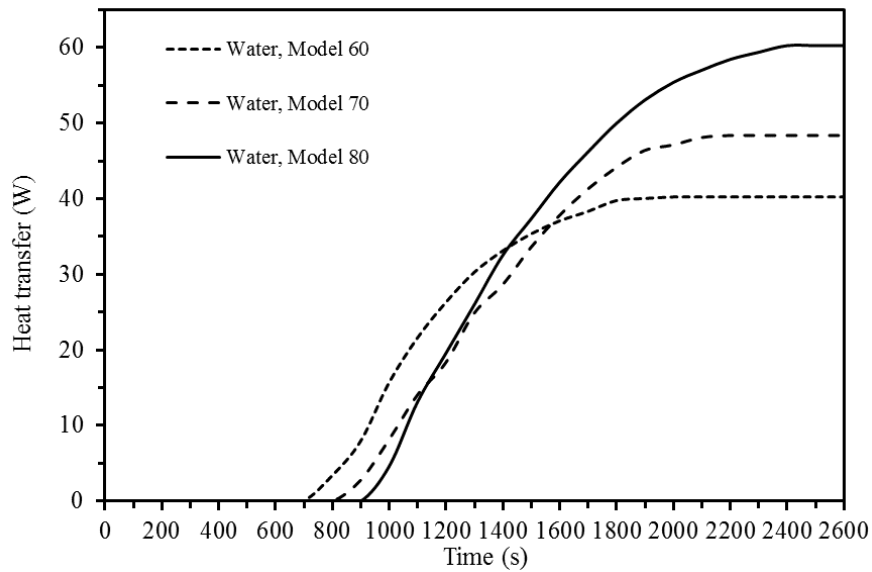

Figure 4.4 Heat transfer of HOHP from model at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of water

Figure 4.5 Heat transfer of HOHP from model at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of ethanol

Figure 4.5 shows the heat transfer profiles from the numerical model under the transient condition of the HOHP with the outer wall temperatures at the evaporator section of  $60, 70$  and  $80^\circ\text{C}$ , and ethanol as the working fluid. It was found that the times

to start-up for the heat transfer of the HOHP from the numerical model were about 500, 600 and 700 s for the temperatures at the evaporator section of 60, 70 and 80°C, respectively. Moreover, this figure also shows the times required to reach the steady state heat transfer from the numerical model for the outer wall temperatures of 60, 70 and 80°C, for which the times required were about 1900, 2100 and 2300 s, respectively. The temperature at the evaporator section of 60°C gave a time to reach the steady state heat transfer that was less than the temperatures at the evaporator section of 70 and 80 °C. The temperature at the evaporator section of 80°C had a higher heat transfer that is more than the temperatures at the evaporator section of 70 and 60°C. The temperature at the evaporator section of 80°C had a greater heat at the HOHP than with the temperatures at the evaporator section of 70 and 60°C. As seen from figure 4.5, the time required to reach the steady state heat transfer and the heat transfer of the HOHP depend on the outer wall temperatures at the evaporator section of the HOHP.

Figure 4.6 shows the heat transfer profiles from the numerical model under the transient condition of the HOHP with the outer wall temperatures at the evaporator section of 60, 70 and 80°C, and R11 as the working fluid. It was found that the times to start-up for the heat transfer of the HOHP from the numerical model were about 400, 500 and 600 s for the temperatures at the evaporator section of 60, 70 and 80°C, respectively. Moreover, this figure also shows the times required to reach the steady state heat transfer from the numerical model for the outer wall temperatures of 60, 70 and 80°C, for which the times required to reach the steady heat transfer were about 1700, 1900 and 2100 s, respectively. The temperature at the evaporator section of 60°C gave a time to reach the steady state heat transfer that was less than the temperatures at the evaporator section of 70 and 80 °C. The temperature at the evaporator section of 80°C has a higher heat transfer than the temperatures at the evaporator section of 70 and 60°C. The temperature at the evaporator section of 80°C has a temperature for the HOHP that is more than the temperatures at the evaporator section of 70 and 60°C. As seen from figure 4.6, the time required to reach the steady state heat transfer and the heat transfer of the HOHP depend on the outer wall temperatures at the evaporator section of the HOHP.

Figure 4.6 Heat transfer of HOHP from model at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of R11

It can be concluded that the times required to reach the steady state heat transfer at the end of the runs from the numerical model of the HOHP used with the working fluid of R11 required a time that was less than the working fluids of ethanol and water. The HOHP used with the working fluid of R11 has a higher heat transfer than the working fluids of ethanol and water. Due to the working fluid of R11 having a lower boiling point than the working fluids of ethanol and water, it has a latent heat of vaporization that is more than those of ethanol and water. When the working fluid of R11 received the heat, it had faster evaporation and more convection than with ethanol and water. Therefore, the working fluid of R11 has a higher heat transfer that is more than the working fluids of ethanol and water.

#### 4.1.3 Heat transfer of HOHP heat exchanger from model

Figure 4.7 shows the heat transfer profiles from the numerical model under the transient condition of the HOHP heat exchanger with the outer wall temperatures at the evaporator section of  $60, 70$  and  $80^\circ\text{C}$  and water as the working fluid. It was found that the times required from start-up to heat transfer for the temperatures at the evaporator section of  $60, 70$  and  $80^\circ\text{C}$  were about  $700, 800$  and  $900$  s, respectively.

Moreover, this figure shows that the times required to reach the steady state heat transfer from the numerical model with the temperatures at the evaporator section of 60, 70 and 80°C were about 2100, 2300 and 2700 s, respectively. The temperature at the evaporator section of 80°C had a higher heat transfer than the temperatures at the evaporator section of 70 and 60°C. The temperature at the evaporator section of 60°C gave a time to reach the steady state heat transfer that was less than the temperatures at the evaporator section of 70 and 80°C. As seen from figure 4.7, the time required to reach the steady state heat transfer and the heat transfer of the HOHP heat exchanger depend on the temperatures input into the evaporator section of the HOHP heat exchanger.

Figure 4.7 Heat transfer of HOHP heat exchanger from model at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of water

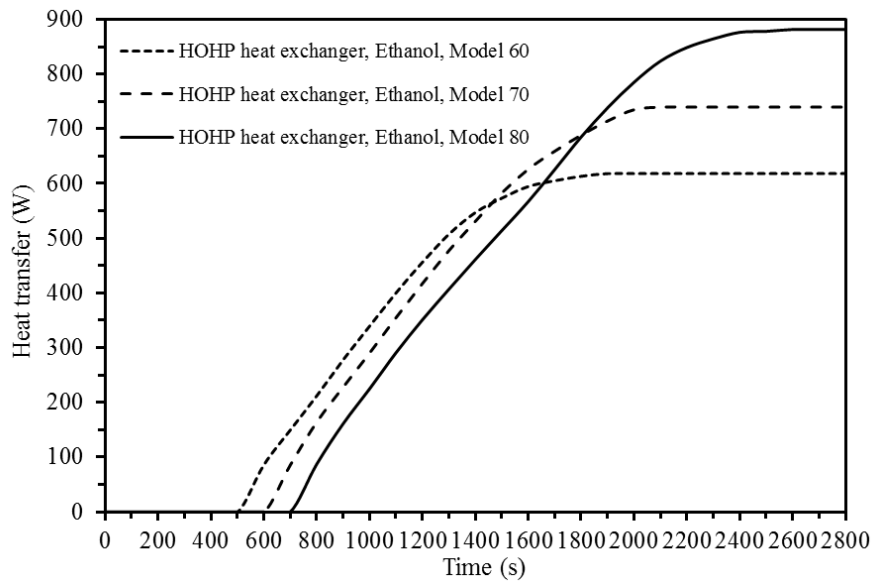

Figure 4.8 Heat transfer of HOHP heat exchanger from model at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of ethanol

Figure 4.8 shows the heat transfer profiles from the numerical model under the transient condition of the HOHP heat exchanger with the temperatures at the evaporator section of 60, 70 and  $80^\circ\text{C}$  and ethanol as the working fluid. It was found that the times required from start-up to heat transfer for the temperatures at the evaporator section of 60, 70 and  $80^\circ\text{C}$  were about 500, 600 and 700 s, respectively. Moreover, this figure shows that the times required to reach the steady state heat transfer from the numerical model with the temperatures at the evaporator section of 60, 70 and  $80^\circ\text{C}$  were about 1900, 2100 and 2600 s, respectively. The temperature at the evaporator section of  $80^\circ\text{C}$  had a higher heat transfer than the temperatures at the evaporator section of 70 and  $60^\circ\text{C}$ , respectively. The temperature at the evaporator section of  $60^\circ\text{C}$  gave a time to reach the steady state heat transfer that was less than the temperatures at the evaporator section of 70 and  $80^\circ\text{C}$ . As seen from figure 4.8, the time required to reach the steady state heat transfer and the heat transfer of the HOHP heat exchanger depend on the temperatures that are input to the evaporator section of the HOHP heat exchanger.

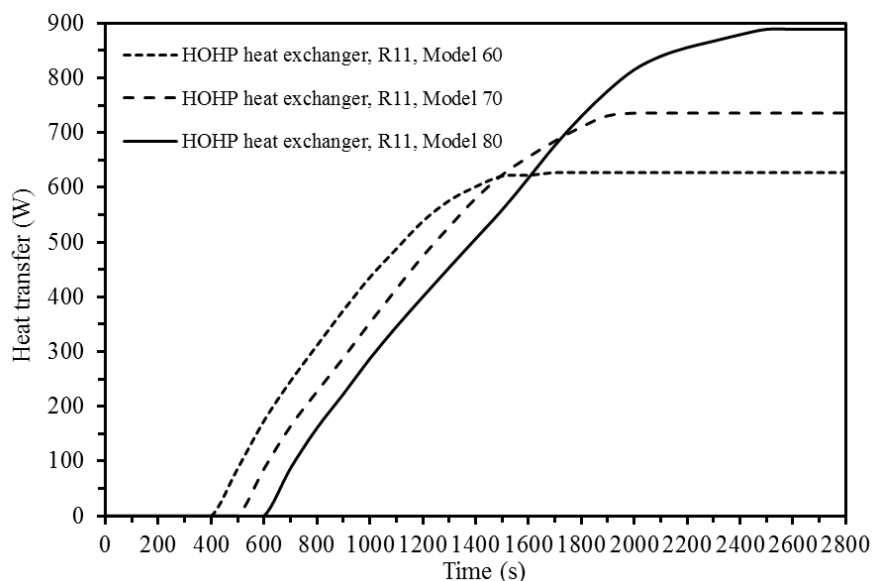

Figure 4.9 Heat transfer of HOHP heat exchanger from model at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of R11

Figure 4.9 shows the heat transfer profiles from the numerical model under the transient condition of the HOHP heat exchanger with the temperatures at the evaporator section of 60, 70 and  $80^\circ\text{C}$  and R11 as the working fluid. It was found that the times required from start-up to heat transfer for the outer wall temperatures at the evaporator section of 60, 70 and  $80^\circ\text{C}$  were about 400, 500 and 600 s, respectively. Moreover, this figure shows that the times required to reach the steady state heat transfer from the numerical model with the temperatures at the evaporator section of 60, 70 and  $80^\circ\text{C}$  were about 1700, 2000 and 2500 s, respectively. The temperature at the evaporator section of  $80^\circ\text{C}$  has a higher heat transfer than the temperatures at the evaporator section of 70 and  $60^\circ\text{C}$ . The temperature at the evaporator section of  $60^\circ\text{C}$  gave a time to reach the steady state heat transfer that was less than the temperatures at the evaporator section of 70 and  $80^\circ\text{C}$ . As seen from figure 4.9, the time required to reach the steady state heat transfer and the heat transfer of the HOHP heat exchanger depend on the temperatures that are input to the evaporator section of the HOHP heat exchanger.

## 4.2 Results from experimental evaluation

### 4.2.1 Temperature at pipe wall of HOHP from experiment

Figure 4.10 shows the temperature profiles at the pipe wall of the HOHP at the evaporator, the adiabatic and the condenser sections from the experimental data with outer wall temperatures at the evaporator section of 60, 70 and 80°C, water as the working fluid and the inner diameter of 1.6 mm. The transient temperature profiles from the figure were plotted as functions of time. It was found that the transient temperature profiles in the evaporator section increased from the initial temperature at the outer pipe wall (25°C) to the temperatures that were input at the evaporator section (60, 70 and 80°C). Since the material of the pipe wall was copper, the thermal conduction was then induced from the outer wall of the pipe to the inner wall of the pipe. In the adiabatic section, heat was induced by thermal conduction from the evaporator section. The temperature of the adiabatic section increased until it reached a steady state, at which it was close to the working temperatures (the average value of the temperatures between the evaporator and the condenser sections). However, the transient temperature profiles in the condenser section decreased because the initial temperature of the outer pipe wall (25°C) was more than the temperature of the condenser section (20°C). The times required to reach the steady state temperature at the end of the runs from the experimental data were about 996, 1256 and 1534 s for the temperatures at the evaporator section of 60, 70 and 80°C, respectively. As seen from figure 4.10, the temperature at the evaporator section increased, and the time required to reach the steady state temperature was increased because the temperature was dependent on the time.

Figure 4.10 Temperature profiles at pipe wall of HOHP from experiment at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of water and  $D_i = 1.6$  mm

Figure 4.11 Temperature profiles at pipe wall of HOHP from experiment at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of water and  $D_i = 1.8$  mm

Figure 4.11 shows the temperature profiles at the pipe wall of the HOHP at the evaporator, the adiabatic and the condenser sections from the experimental data with outer wall temperatures at the evaporator section of 60, 70 and 80°C, water as the working fluid and the inner diameter of 1.8 mm. The transient temperature profiles from the figure were plotted as functions of time. It was found that the transient temperature profiles in the evaporator section increased from the initial temperature at the outer pipe wall (25°C) to the temperatures that were input at the evaporator section (60, 70 and 80°C). Since the material of the pipe wall was copper, the thermal conduction was then induced from the outer wall of the pipe to the inner wall of the pipe. In the adiabatic section, heat was induced by thermal conduction from the evaporator section. The temperature of the adiabatic section increased until it reached a steady state, at which it was close to the working temperatures (the average value of the temperatures between the evaporator and the condenser sections). However, the transient temperature profiles in the condenser section decreased because the initial temperature of the outer pipe wall (25°C) was more than the temperature of the condenser section (20°C). The times required to reach the steady state temperature at the end of the runs from the experimental data were about 1196, 1274 and 1648 s for the temperatures at the evaporator section of 60, 70 and 80°C, respectively. As seen from figure 4.11, the temperature at the evaporator section increased, and the time required to reach the steady state temperature was increased because the temperature was dependent on the time.

Figure 4.12 shows the temperature profiles at the pipe wall of the HOHP at the evaporator, the adiabatic and the condenser sections from the experimental data with the outer wall temperatures at the evaporator section of 60, 70 and 80°C, water as the working fluid and the inner diameter of 2.0 mm. The transient temperature profiles from the figure were plotted as functions of time. It was found that the transient temperature profiles in the evaporator section increased from the initial temperature at the outer pipe wall (25°C) to the temperatures that were input at the evaporator section (60, 70 and 80°C). Since the material of the pipe wall was copper, the thermal conduction was then induced from the outer wall of the pipe to the inner wall of the pipe. In the adiabatic section, heat was induced by thermal conduction from the evaporator section. The

temperature of the adiabatic section increased until it reached a steady state, at which it was close to the working temperature (the average value of the temperature between the evaporator and the condenser sections). However, the transient temperature profiles in the condenser section decreased because the initial temperature of the outer pipe wall (25°C) was more than the temperature of the condenser section (20°C). The times required to reach the steady state temperature at the end of the runs from the experimental data were about 1216, 1368 and 1698 s for the temperatures at the evaporator section of 60, 70 and 80°C, respectively. As seen from figure 4.12, the temperature at the evaporator section increased, and the time required to reach the steady state temperature was increased because the temperature was dependent on the time.

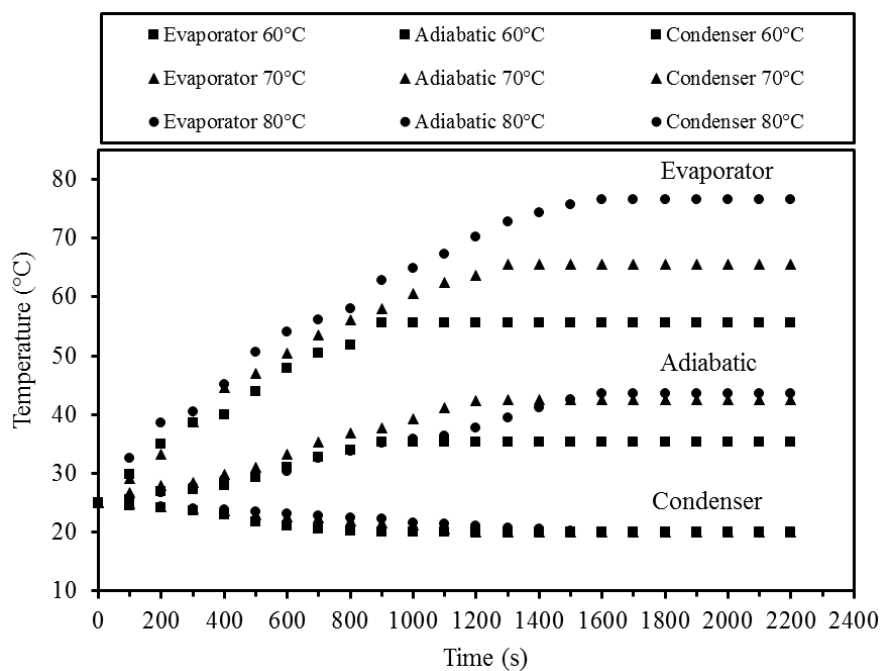

Figure 4.12 Temperature profiles at pipe wall of HOHP from experiment at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of water and  $D_i = 2.0$  mm

Figure 4.13 Temperature profiles at pipe wall of HOHP from experiment at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of ethanol and  $D_i = 1.6$  mm

Figure 4.13 shows the temperature profiles at the pipe wall of the HOHP at the evaporator, the adiabatic and the condenser sections from the experimental data with the outer wall temperatures at the evaporator section of  $60, 70$  and  $80^\circ\text{C}$ , ethanol as the working fluid and the inner diameter of  $1.6$  mm. The transient temperature profiles from the figure were plotted as functions of time. It was found that the transient temperature profiles in the evaporator section increased from the initial temperature at the outer pipe wall ( $25^\circ\text{C}$ ) to the temperatures that were input at the evaporator section ( $60, 70$  and  $80^\circ\text{C}$ ). Since the material of the pipe wall was copper, the thermal conduction was then induced from the outer wall of the pipe to the inner wall of the pipe. In the adiabatic section, heat was induced by thermal conduction from the evaporator section. The temperature of the adiabatic section increased until it reached a steady state, at which it was close to the working temperatures (the average value of the temperatures between the evaporator and the condenser sections). However, the transient temperature profiles in the condenser section decreased because the initial temperature of the outer pipe wall ( $25^\circ\text{C}$ ) was more than the temperature of the condenser section ( $20^\circ\text{C}$ ). The times required to reach the steady state temperature at the end of the runs from the

experimental data were about 940, 1316 and 1704 s for the temperatures at the evaporator section of 60, 70 and 80°C, respectively. As seen from figure 4.13, the temperature at the evaporator section increased, and the time required to reach the steady state temperature was increased because the temperature was dependent on the time.

Figure 4.14 shows the temperature profiles at the pipe wall of the HOHP at the evaporator, the adiabatic and the condenser sections from the experimental data with the outer wall temperatures at the evaporator section of 60, 70 and 80°C, ethanol as the working fluid and the inner diameter of 1.8 mm. The transient temperature profiles from the figure were plotted as functions of time. It was found that the transient temperature profiles in the evaporator section increased from the initial temperature at the outer pipe wall (25°C) to the temperatures that were input at the evaporator section (60, 70 and 80°C). Since the material of the pipe wall was copper, the thermal conduction was then induced from the outer wall of the pipe to the inner wall of the pipe. In the adiabatic section, heat was induced by thermal conduction from the evaporator section. The temperature of the adiabatic section increased until it reached a steady state, at which it was close to the working temperatures (the average value of the temperatures between the evaporator and the condenser sections). However, the transient temperature profiles in the condenser section decreased because the initial temperature of the outer pipe wall (25°C) was more than the temperature of the condenser section (20°C). The times required to reach the steady state temperature at the end of the runs from the experimental data were about 1032, 1360 and 1746 s for the temperatures at the evaporator section of 60, 70 and 80°C, respectively. As seen from figure 4.14, the temperature at the evaporator section increased, and the time required to reach the steady state temperature was increased because the temperature was dependent on the time.

Figure 4.14 Temperature profiles at pipe wall of HOHP from experiment at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of ethanol and  $D_i = 1.8$  mm

Figure 4.15 shows the temperature profiles at the pipe wall of the HOHP at the evaporator, the adiabatic and the condenser sections from the experimental data with the outer wall temperatures at the evaporator section of  $60, 70$  and  $80^\circ\text{C}$ , ethanol as the working fluid and the inner diameter of  $2.0$  mm. The transient temperature profiles from the figure were plotted as functions of time. It was found that the transient temperature profiles in the evaporator section increased from the initial temperature at the outer pipe wall ( $25^\circ\text{C}$ ) to the temperatures that were input at the evaporator section ( $60, 70$  and  $80^\circ\text{C}$ ). Since the material of the pipe wall was copper, the thermal conduction was then induced from the outer wall of the pipe to the inner wall of the pipe. In the adiabatic section, heat was induced by thermal conduction from the evaporator section. The temperature of the adiabatic section increased until it reached a steady state, at which it was close to the working temperatures (the average value of the temperatures between the evaporator and the condenser sections). However, the transient temperature profiles in the condenser section decreased because the initial temperature of the outer pipe wall ( $25^\circ\text{C}$ ) was more than the temperature of the condenser section ( $20^\circ\text{C}$ ). The times

required to reach the steady state temperature at the end of the runs from the experimental data were about 1130, 1430, and 1806 s for the temperatures at the evaporator section of 60, 70 and 80°C, respectively. As seen from figure 4.15, the temperature at the evaporator section increased, and the time required to reach the steady state temperature was increased because the temperature was dependent on the time.

Figure 4.15 Temperature profiles at pipe wall of HOHP from experiment at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of ethanol and  $D_i = 2.0$  mm

Figure 4.16 Temperature profiles at pipe wall of HOHP from experiment at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of R11 and  $D_i = 1.6$  mm

Figure 4.16 shows the temperature profiles at the pipe wall of the HOHP at the evaporator, the adiabatic and the condenser sections from the experimental data with the outer wall temperatures at the evaporator section of  $60, 70$  and  $80^\circ\text{C}$ , R11 as the working fluid and the inner diameter of  $1.6$  mm. The transient temperature profiles from the figure were plotted as functions of time. It was found that the transient temperature profiles in the evaporator section increased from the initial temperature at the outer pipe wall ( $25^\circ\text{C}$ ) to the temperatures that were input at the evaporator section ( $60, 70$  and  $80^\circ\text{C}$ ). Since the material of the pipe wall was copper, the thermal conduction was then induced from the outer wall of the pipe to the inner wall of the pipe. In the adiabatic section, heat was induced by thermal conduction from the evaporator section. The temperature of the adiabatic section increased until it reached a steady state, at which it was close to the working temperatures (the average value of the temperatures between the evaporator and the condenser sections). However, the transient temperature profiles in the condenser section decreased because the initial temperature at the outer pipe wall ( $25^\circ\text{C}$ ) was more than the temperature of the condenser section ( $20^\circ\text{C}$ ). The times

required to reach the steady state temperature at the end of the runs from the experimental data were about 906, 1282 and 1556 s for the temperatures at the evaporator section of 60, 70 and 80°C, respectively. As seen from figure 4.16, the temperature at the evaporator section increased, and the time required to reach the steady state temperature was increased because the temperature was dependent on the time.

Figure 4.17 Temperature profiles at pipe wall of HOHP from experiment at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of R11 and  $D_i = 1.8$  mm

Figure 4.17 shows the temperature profiles at the pipe wall of the HOHP at the evaporator, the adiabatic and the condenser sections from the experimental data with the outer wall temperatures at the evaporator section of 60, 70 and 80°C, R11 as the working fluid and the inner diameter of 1.8 mm. The transient temperature profiles from the figure were plotted as functions of time. It was found that the transient temperature profiles in the evaporator section increased from the initial temperature at the outer pipe wall (25°C) to the temperatures that were input at the evaporator section (60, 70 and 80°C). Since the material of the pipe wall was copper, the thermal conduction was then

induced from the outer wall of the pipe to the inner wall of the pipe. In the adiabatic section, heat was induced by thermal conduction from the evaporator section. The temperature of the adiabatic section increased until it reached a steady state, at which it was close to the working temperatures (the average value of the temperatures between the evaporator and the condenser sections). However, the transient temperature profiles in the condenser section decreased because the initial temperature of the outer pipe wall (25°C) was more than the temperature of the condenser section (20°C). The times required to reach the steady state temperature at the end of the runs from the experimental data were about 922, 1294 and 1586 s for the temperatures at the evaporator section of 60, 70 and 80°C, respectively. As seen from figure 4.17, the temperature at the evaporator section increased, and the time required to reach the steady state temperature was increased because the temperature was dependent on the time.

Figure 4.18 Temperature profiles at pipe wall of HOHP from experiment at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of R11 and  $D_i = 2.0$  mm

Figure 4.18 shows the temperature profiles at the pipe wall of the HOHP at the evaporator, the adiabatic and the condenser sections from the experimental data with the outer wall temperatures at the evaporator section of 60, 70 and 80°C, R11 as the working fluid and the inner diameter of 2.0 mm. The transient temperature profiles from the figure were plotted as functions of time. It was found that the transient temperature profiles in the evaporator section increased from the initial temperature at the outer pipe wall (25°C) to the temperatures that were input at the evaporator section (60, 70 and 80°C). Since the material of the pipe wall was copper, the thermal conduction was then induced from the outer wall of the pipe to the inner wall of the pipe. In the adiabatic section, heat was induced by thermal conduction from the evaporator section. The temperature of the adiabatic section increased until it reached a steady state, at which it was close to the working temperatures (the average value of the temperatures between the evaporator and the condenser sections). However, the transient temperature profiles in the condenser section decreased because the initial temperature of the outer pipe wall (25°C) was more than the temperature of the condenser section (20°C). The times required to reach the steady state temperature at the end of the runs from the experimental data were about 1010, 1380 and 1618 s for the temperatures at the evaporator section of 60, 70 and 80°C, respectively. As seen from figure 4.18, the temperature at the evaporator section increased, and the time required to reach the steady state temperature was increased because the temperature was dependent on the time.

#### 4.2.2 Heat transfer of HOHP from experiment

Figure 4.19 shows the heat transfer profiles from the experimental data under the transient condition of the HOHP with the temperatures at the evaporator section of 60, 70 and 80°C, water as the working fluid and the inner diameter of 1.6 mm. It was found that when the temperatures were applied to the evaporator section of the HOHP, the heat transfer did not occur at the start-up of the experiment. The heat transfer occurred at the times of 640, 752 and 880 s for the temperatures at the evaporator section of 60, 70 and 80°C, respectively. Due to the working fluid within the HOHP not receiving the heat from the outer wall of the evaporator section of the HOHP

to boil the working fluid within the HOHP. When the working fluid received enough heat, the working fluid will boil and there will be convection of the heat from the evaporator section to the condenser section of the HOHP. Moreover, this figure shows that the times required to reach the steady state heat transfer from the experimental data with the temperatures at the evaporator section of 60, 70 and 80°C were about 1724, 1934 and 2132 s, respectively. As seen from figure 4.19, the time required to reach the steady state heat transfer depends on the temperatures that are input to the evaporator section of the HOHP. It should be mentioned that the heat recovered at the condenser section is always lower than the heat added to the evaporator section due to uncontrolled heat losses from the experimental setup.

Figure 4.19 Heat transfer of HOHP from experiment at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of water and  $D_i = 1.6$  mm

Figure 4.20 shows the heat transfer profiles from the experimental data under the transient condition of the HOHP with the temperatures at the evaporator section of 60, 70 and  $80^\circ\text{C}$ , water as the working fluid and the inner diameter of 1.8 mm. It was found that when applying the temperatures to the evaporator section of the HOHP, the heat transfer did not occur at the start-up of the experiment. The heat

transfer occurs at the times of 610, 776 and 894 s for the temperatures at the evaporator section of 60, 70 and 80°C, respectively. Due to the working fluid within the HOHP not receiving heat from the outer wall of the evaporator section of the HOHP to boil the working fluid within the HOHP. When the working fluid has received enough heat, the working fluid will boil and there will be convection of the heat from the evaporator section to the condenser section of the HOHP. Moreover, this figure shows that the times required to reach the steady state heat transfer from the experimental data with the temperatures at the evaporator section of 60, 70 and 80°C were about 1800, 2082 and 2210 s, respectively. As seen from figure 4.20, the time required to reach the steady state heat transfer depends on the temperatures that are input to the evaporator section of the HOHP. It should be mentioned that the heat recovered at the condenser section is always lower than the heat added to the evaporator section due to uncontrolled heat losses from the experimental setup.

Figure 4.20 Heat transfer of HOHP from experiment at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of water and  $D_i = 1.8$  mm

Figure 4.21 Heat transfer of HOHP from experiment at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of water and  $D_i = 2.0$  mm

Figure 4.21 shows the heat transfer profiles from the experimental data under the transient condition of the HOHP with the temperatures at the evaporator section of  $60, 70$  and  $80^\circ\text{C}$ , water as the working fluid and the inner diameter of  $2.0$  mm. It was found that when applying the temperatures to the evaporator section of the HOHP, the heat transfer did not occur at the start-up of the experiment. The heat transfer occurred at the times of  $644, 742$  and  $852$  s for the temperatures at the evaporator section of  $60, 70$  and  $80^\circ\text{C}$ , respectively. Due to the working fluid within the HOHP not receiving the heat from the outer wall of the evaporator section of the HOHP for the boiling of the working fluid within the HOHP. When the working fluid has received enough heat, the working fluid will boil and there is convection of the heat from the evaporator section to the condenser section of the HOHP. Moreover, this figure shows that the times required to reach the steady state heat transfer from the experimental data with the temperatures at the evaporator section of  $60, 70$  and  $80^\circ\text{C}$  were about  $1826, 2116$  and  $2290$  s, respectively. As seen from figure 4.21, the time required to reach the steady state heat transfer depends on the temperatures that are input to the evaporator section of the HOHP. It should be mentioned that the heat

recovered at the condenser section is always lower than the heat added to the evaporator section due to uncontrolled heat losses from the experimental setup.

Figure 4.22 Heat transfer of HOHP from experiment at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of ethanol and  $D_i = 1.6$  mm

Figure 4.22 shows the heat transfer profiles from the experimental data under the transient condition of the HOHP with the temperatures at the evaporator section of 60, 70 and  $80^\circ\text{C}$ , ethanol as the working fluid and the inner diameter of 1.6 mm. It was found that when applying the temperatures to the evaporator section of the HOHP, the heat transfer did not occur at the start-up of the experiment. The heat transfer occurred at the times of 502, 592 and 602 s for the temperatures at the evaporator section of 60, 70 and  $80^\circ\text{C}$ , respectively. Due to the working fluid within the HOHP not receiving the heat from the outer wall of the evaporator section of the HOHP to boil the working fluid within the HOHP. When the working fluid has received the enough heat, the working fluid will boil and there is convection of the heat from the evaporator section to the condenser section of the HOHP. Moreover, this figure shows that the times required to reach the steady state heat transfer from the experimental data with the temperatures at the evaporator section of 60, 70 and  $80^\circ\text{C}$  were about 1620,

1836 and 2002 s, respectively. As seen from figure 4.22, the time required to reach the steady state heat transfer depends on the temperatures that are input to the evaporator section of the HOHP. It should be mentioned that the heat recovered at the condenser section is always lower than the heat added to the evaporator section due to uncontrolled heat losses from the experimental setup.

Figure 4.23 Heat transfer of HOHP from experiment at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of ethanol and  $D_i = 1.8$  mm

Figure 4.23 shows the heat transfer profiles from the experimental data under the transient condition of the HOHP with the temperatures at the evaporator section of 60, 70 and  $80^\circ\text{C}$ , ethanol as the working fluid and the inner diameter of 1.8 mm. It was found that when applying the temperatures to the evaporator section of the HOHP, the heat transfer did not occur at the start-up of the experiment. The heat transfer occurred at the times of 504, 600 and 650 s for the temperatures at the evaporator section of 60, 70 and  $80^\circ\text{C}$ , respectively. Due to the working fluid within the HOHP not receiving the heat from the outer wall of the evaporator section of the HOHP enough to boil the working fluid within the HOHP. When the working fluid has received enough heat, the working fluid will boil and there is convection of the heat

from the evaporator section to the condenser section of the HOHP. Moreover, this figure shows that the times required to reach the steady state heat transfer from the experimental data with the temperatures at the evaporator section of 60, 70 and 80°C were about 1754, 1866 and 2092 s, respectively. As seen from figure 4.23, the time required to reach the steady state heat transfer depends on the temperatures that are input to the evaporator section of the HOHP. It should be mentioned that the heat recovered at the condenser section is always lower than the heat added to the evaporator section due to uncontrolled heat losses from the experimental setup.

Figure 4.24 Heat transfer of HOHP from experiment at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of ethanol and  $D_i = 2.0$  mm

Figure 4.24 shows the heat transfer profiles from the experimental data under the transient condition of the HOHP with the temperatures at the evaporator section of 60, 70 and  $80^\circ\text{C}$ , ethanol as the working fluid and the inner diameter as 2.0 mm. It was found that when applying the temperatures to the evaporator section of the HOHP, the heat transfer did not occur at the start-up of the experiment. The heat transfer occurred at the times of 514, 554 and 630 s for the temperatures at the evaporator section of 60, 70 and  $80^\circ\text{C}$ , respectively. Due to the working fluid within the

HOHP not receiving the heat from the outer wall of the evaporator section of the HOHP to boil the working fluid within the HOHP. When the working fluid has received enough heat, the working fluid will boil and there is convection of the heat from the evaporator section to the condenser section of the HOHP. Moreover, this figure shows that the times required to reach the steady state heat transfer from the experimental data with the temperatures of the evaporator section of 60, 70 and 80°C were about 1786, 1880 and 2142 s, respectively. As seen from figure 4.24, the time required to reach the steady state heat transfer depends on the temperatures that are input to the evaporator section of the HOHP. It should be mentioned that the heat recovered at the condenser section is always lower than the heat added to the evaporator section due to uncontrolled heat losses from the experimental setup.

Figure 4.25 Heat transfer of HOHP from experiment at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of R11 and  $D_i = 1.6$  mm

Figure 4.25 shows the heat transfer profiles from the experimental data under the transient condition of the HOHP with the temperatures at the evaporator section of 60, 70 and  $80^\circ\text{C}$ , R11 as the working fluid and the inner diameter of 1.6 mm. It was found that when applying the temperatures to the evaporator section of the

HOHP, the heat transfer did not occur at the start-up of the experiment. The heat transfer occurred at the times of 388, 410 and 480 s for the temperatures at the evaporator section of 60, 70 and 80°C, respectively. Due to the working fluid within the HOHP not received the heat from the outer wall of the evaporator section of the HOHP to boil the working fluid within the HOHP. When the working fluid has received enough heat, the working fluid will boil and there is convection of the heat from the evaporator section to the condenser section of the HOHP. Moreover, this figure shows that the times required to reach the steady state heat transfer from the experimental data with the temperatures at the evaporator section of 60, 70 and 80°C were about 1584, 1760 and 1890 s, respectively. As seen from figure 4.25, the time required to reach the steady state heat transfer depends on the temperatures that are input to the evaporator section of the HOHP. It should be mentioned that the heat recovered at the condenser section is always lower than the heat added to the evaporator section due to uncontrolled heat losses from the experimental setup.

Figure 4.26 Heat transfer of HOHP from experiment at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of R11 and  $D_i = 1.8$  mm

Figure 4.26 shows the heat transfer profiles from the experimental data under the transient condition of the HOHP with the temperatures at the evaporator section of 60, 70 and 80°C, R11 as the working fluid and the inner diameter of 1.8 mm. It was found that when applying the temperatures to the evaporator section of the HOHP, the heat transfer did not occur at the start-up of the experiment. The heat transfer occurred at the times of 384, 444 and 504 s for the temperatures at the evaporator section of 60, 70 and 80°C, respectively. Due to the working fluid within the HOHP not receiving the heat from the outer wall of the evaporator section of the HOHP to boil the working fluid within the HOHP. When the working fluid has received enough heat, the working fluid will boil and there is convection of the heat from the evaporator section to the condenser section of the HOHP. Moreover, this figure shows that the times required to reach the steady state heat transfer from the experimental data with the temperatures at the evaporator section of 60, 70 and 80°C were about 1612, 1790 and 1915 s, respectively. As seen from figure 4.26, the time required to reach the steady state heat transfer depends on the temperatures that are input to the evaporator section of the HOHP. It should be mentioned that the heat recovered at the condenser section is always lower than the heat added to the evaporator section due to uncontrolled heat losses from the experimental setup.

Figure 4.27 shows the heat transfer profiles from the experimental data under the transient condition of the HOHP with the temperatures at the evaporator section of 60, 70 and 80°C, R11 as the working fluid and the inner diameter of 2.0 mm. It was found that when applying the temperatures to the evaporator section of the HOHP, the heat transfer did not occur at the start-up of the experiment. The heat transfer occurred at the times of 396, 464 and 520 s for the temperatures at the evaporator section of 60, 70 and 80°C, respectively. Due to the working fluid within the HOHP not receiving the heat from the outer wall of the evaporator section of the HOHP to boil the working fluid within the HOHP. When the working fluid has received enough heat, the working fluid will boil and there is convection of the heat from the evaporator section to the condenser section of the HOHP. Moreover, this figure shows that the times required to reach the steady state heat transfer from the experimental data with the temperatures at the evaporator section of 60, 70 and 80°C were about 1634,

1818 and 1952 s, respectively. As seen from figure 4.27, the time required to reach the steady state heat transfer depends on the temperatures that are input to the evaporator section of the HOHP. It should be mentioned that the heat recovered at the condenser section is always lower than the heat added to the evaporator section due to uncontrolled heat losses from the experimental setup.

Figure 4.27 Heat transfer of HOHP from experiment at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of R11 and  $D_i = 2.0$  mm

#### 4.2.3 Heat transfer of HOHP heat exchanger from experiment

Figure 4.28 shows the heat transfer profiles from the experimental data under the transient condition of the HOHP heat exchanger with the temperatures at the evaporator section of 60, 70 and  $80^\circ\text{C}$ , R11 as the working fluid and the inner diameter of 2.0 mm. It was found that the times to start-up for the heat transfer of the HOHP heat exchanger with the temperatures at the evaporator section of 60, 70 and  $80^\circ\text{C}$  were about 368, 456 and 544 s, respectively. Moreover, this figure shows that the times required to reach the steady state heat transfer of the HOHP heat exchanger for the temperatures at the evaporator section of 60, 70 and  $80^\circ\text{C}$  were about 1634, 1912 and 2378 s, respectively. As seen from the figure, the times required to reach the steady

state heat transfer depend on the temperatures that are input to the evaporator section of the HOHP heat exchanger.

Figure 4.28 Heat transfer of HOHP heat exchanger from experiment at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of R11 and  $D_i = 2.0$  mm

### 4.3 Comparison of results from model and experiment

#### 4.3.1 Comparison of temperature at pipe wall of HOHP

The results of the temperatures for the pipe wall of the HOHP at the evaporator, the adiabatic and the condenser sections from the numerical model are compared with the experimental data, and are presented in figures 4.29, 4.30 and 4.31, respectively, for the outer wall temperatures at the evaporator section of  $60, 70$  and  $80^\circ\text{C}$ , working fluid of water and the inner diameter of  $2.0$  mm. The transient condition temperature profiles from the numerical model and the experimental data were plotted as functions of time. The temperatures from the experimental data were the average values for the evaporator, the adiabatic and the condenser sections. It was found that the transient temperature profiles in the evaporator section increased from the initial temperature of the pipe wall ( $25^\circ\text{C}$ ) to the outer wall temperatures that were input to the evaporator section ( $60, 70$  and  $80^\circ\text{C}$ ). Since the pipe wall was copper, the thermal

conduction was then induced from the outer wall of the pipe to the inner wall of the pipe. In the adiabatic section, heat was induced by thermal conduction from the evaporator section, and the temperature of the adiabatic section increased until it reached a steady state temperature, at which it was close to the working temperatures (the average value of the temperatures between the evaporator and the condenser sections). However, the transient temperature profiles for the condenser section decreased because the initial temperature (25°C) was more than the outer wall temperature of the condenser section (20°C). The times required to reach the steady state temperature at the end of the runs from the numerical model were about 1300, 1600 and 2000 s for the outer wall temperatures at the evaporator section of 60, 70 and 80°C, respectively. As seen from the figures, when the temperatures at the evaporator section increased, the time required to reach the steady state temperature increased because the temperature was dependent on the time. The times required to reach the steady state temperature from the experiment were about 1216, 1368 and 1698 s for the outer wall temperatures at the evaporator section of 60, 70 and 80°C, respectively.

The solid lines correspond to the temperatures of the evaporator, the adiabatic, and the condenser sections from the numerical model predicting the response of the temperature with time, and the symbols correspond to the experimentally measured temperature average values. As seen from figures 4.29, 4.30 and 4.31, it was found that the comparisons between the results from the numerical model and the experimental data response curves are excellent for all three sections. The time required to reach the steady state temperature for the numerical model was not equal to the experiment because the numerical model was assumed to have no losses in the calculation, but the experiment had errors from some uncontrollable parameters. As seen from all figures, the time required to reach the steady state temperature between the numerical model and the experiment results was different, and the differences were 6.6%, 14.5% and 15.1% for the outer wall temperatures at the evaporator section of 60, 70 and 80°C, respectively. The time required to reach the steady state temperature is an important parameter for the start-up of the HOHP. The two values from the numerical model and the experimental data are in good agreement.

Figure 4.29 Compared temperature profiles at pipe wall of HOHP from model and experiment at  $T_e = 60^\circ\text{C}$  with working fluid of water

Figure 4.30 Compared temperature profiles at pipe wall of HOHP from model and experiment at  $T_e = 70^\circ\text{C}$  with working fluid of water

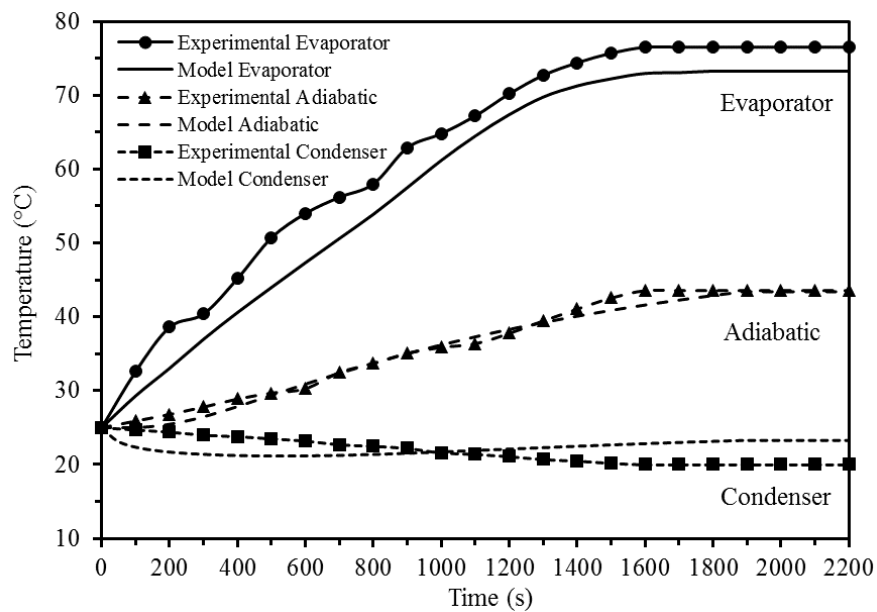

Figure 4.31 Compared temperature profiles at pipe wall of HOHP from model and experiment at  $T_e = 80^\circ\text{C}$  with working fluid of water

The results of the temperatures of the pipe wall of the HOHP at the evaporator, the adiabatic and the condenser sections from the numerical model are compared with the experimental data, and are presented in figures 4.32, 4.33 and 4.34, respectively, for the outer wall temperatures at the evaporator section of 60, 70 and 80°C, the working fluid as ethanol and the inner diameter of 2.0 mm. The transient condition temperature profiles from the numerical model and the experimental data were plotted as functions of time. The temperature from the experimental data was the average values for the evaporator, the adiabatic and the condenser sections. It was found that the transient temperature profiles in the evaporator section increased from the initial temperature of the pipe wall (25°C) to the outer wall temperatures that were input to the evaporator section (60, 70 and 80°C). Since the pipe wall was copper, the thermal conduction was then induced from the outer wall of the pipe to the inner wall of the pipe. In the adiabatic section, heat was induced by thermal conduction from the evaporator section, and the temperature of the adiabatic section increased until it reached a steady state temperature, at which it was close to the working temperatures (the average value of the temperatures between the evaporator and the condenser sections). However, the transient temperature profiles in the condenser section

decreased because the initial temperature ( $25^{\circ}\text{C}$ ) was more than the outer wall temperature of the condenser section ( $20^{\circ}\text{C}$ ). The times required to reach the steady state temperature at the end of the runs from the numerical model were about 1200, 1500 and 1900 s for the outer wall temperatures at the evaporator section of 60, 70 and  $80^{\circ}\text{C}$ , respectively. As seen from the figures, when the temperatures at the evaporator section increased, the time required to reach the steady state temperature was increased because the temperature was dependent on the time. The times required to reach the steady state temperature from the experiment were about 1130, 1430 and 1806 s for the outer wall temperatures at the evaporator section of 60, 70 and  $80^{\circ}\text{C}$ , respectively.

The solid lines correspond to the temperatures of the evaporator, the adiabatic and the condenser sections from the numerical model predicting the response of the temperature with time and the symbols correspond to the experimentally measured temperature average values. As seen from figures 4.32, 4.33 and 4.34, it was found that the comparisons between the results from the numerical model and the experimental data response curves are excellent for all three sections. The time required to reach the steady state temperature for the numerical model was not equal to the experiment because the numerical model was assumed to have no losses in the calculation, but the experiment had errors from some uncontrollable parameters. As seen from all figures, the time required to reach the steady state temperature between the numerical model and the experiment results was different, and the differences were 5.8%, 4.7% and 4.9% for the outer wall temperatures at the evaporator section of 60, 70 and  $80^{\circ}\text{C}$ , respectively. The time required to reach the steady state temperature is an important parameter for the start-up of the HOHP. The two values from the numerical model and the experimental data are in good agreement.

Figure 4.32 Compared temperature profiles at pipe wall of HOHP from model and experiment at  $T_e = 60^\circ\text{C}$  with working fluid of ethanol

Figure 4.33 Compared temperature profiles at pipe wall of HOHP from model and experiment at  $T_e = 70^\circ\text{C}$  with working fluid of ethanol

Figure 4.34 Compared temperature profiles at pipe wall of HOHP from model and experiment at  $T_e = 80^\circ\text{C}$  with working fluid of ethanol

The results of the temperatures for the pipe wall of the HOHP at the evaporator, the adiabatic and the condenser sections from the numerical model are compared with the experimental data and are presented in figures 4.35, 4.36 and 4.37, respectively, for the outer wall temperatures at the evaporator section of 60, 70 and 80°C, the working fluid as R11 and the inner diameter of 2.0 mm. The transient condition temperature profiles from the numerical model and the experimental data were plotted as functions of time. The temperature from the experimental data was the average values for the evaporator, the adiabatic and the condenser sections. It was found that the transient temperature profiles in the evaporator section increased from the initial temperature of the pipe wall (25°C) to the outer wall temperatures that were input to the evaporator section (60, 70 and 80°C). Since the pipe wall was copper, the thermal conduction was then induced from the outer wall of the pipe to the inner wall of the pipe. In the adiabatic section, heat was induced by thermal conduction from the evaporator section, and the temperature of the adiabatic section increased until it reached a steady state temperature, at which it was close to the working temperatures (the average value of the temperatures between the evaporator and the condenser sections). However, the transient temperature profiles in the condenser section

decreased because the initial temperature ( $25^{\circ}\text{C}$ ) was more than the outer wall temperature of the condenser section ( $20^{\circ}\text{C}$ ). The times required to reach the steady state temperature at the end of the runs from the numerical model were about 1100, 1400 and 1800 s for the outer wall temperatures at the evaporator section of 60, 70 and  $80^{\circ}\text{C}$ , respectively. As seen from the figures, when the temperatures of the evaporator section increased, the time required to reach the steady state temperature was increased because the temperature was dependent on the time. The times required to reach the steady state temperature from the experiment were about 1010, 1380 and 1618 s for the outer wall temperatures at the evaporator section of 60, 70 and  $80^{\circ}\text{C}$ , respectively.

The solid lines correspond to the temperatures of the evaporator, the adiabatic and the condenser sections from the numerical model predicting the response of the temperature with time and the symbols correspond to the experimentally measured temperature average values. As seen from figures 4.35, 4.36 and 4.37, it was found that the comparisons between the results from the numerical model and the experimental data response curves are excellent for all three sections. The time required to reach the steady state temperature for the numerical model was not equal to the experiment because the numerical model was assumed to have no losses in the calculation, but the experiment had errors from some uncontrollable parameters. As seen from all the figures, the time required to reach the steady state temperature between the numerical model and the experimental results was different, and the differences were 8.2%, 1.4% and 10.1% for the outer wall temperatures at the evaporator section of 60, 70 and  $80^{\circ}\text{C}$ , respectively. The time required to reach the steady state temperature is an important parameter for the start-up of the HOHP. The two values from the numerical model and the experimental data are in good agreement.

Figure 4.36 Compared temperature profiles at pipe wall of HOHP from model and experiment at  $T_e = 70^\circ\text{C}$  with working fluid of R11

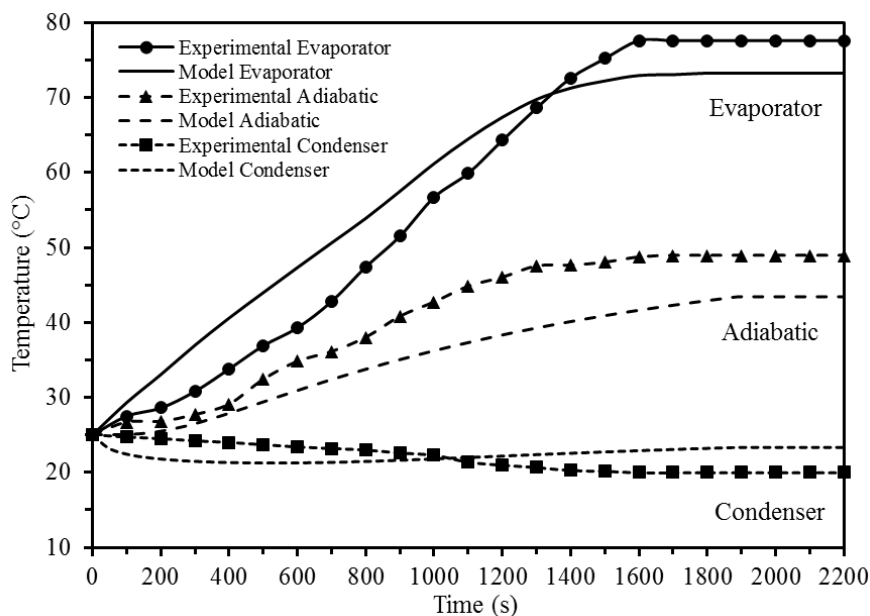

Figure 4.37 Compared temperature profiles at pipe wall of HOHP from model and experiment at  $T_e = 80^\circ\text{C}$  with working fluid of R11

#### 4.3.2 Comparison of heat transfer of HOHP

Figure 4.38 shows the comparisons of the heat transfer profiles from the numerical model and the experimental data under the transient condition of the HOHP with the temperatures at the evaporator section of 60, 70 and 80°C, the working fluid as water and the inner diameter of 2.0 mm. The figure identifies that the times to start-up for the heat transfer of the HOHP from the numerical model and the experimental data with the temperature at the evaporator section of 60°C were 700 and 644 s, respectively. The times to start-up for the heat transfer of the HOHP from the numerical model and the experimental data with the temperature at the evaporator section of 70°C were 800 and 742 s, respectively. The times to start-up for the heat transfer of the HOHP from the numerical model and the experimental data with the temperature at the evaporator section of 80°C were 900 and 852 s, respectively. Moreover, this figure shows that the times required to reach the steady state heat transfer from the numerical model and the experimental data with the temperature at the evaporator section of 60°C were 2000 and 1826 s, respectively. The times required to reach the steady state heat transfer from the numerical model and the experimental data with the temperature at the evaporator section of 70°C were 2200 and 2116 s, respectively. The times required to reach the

steady state heat transfer from the numerical model and the experimental data with the temperature at the evaporator section of 60°C were 2400 and 2290 s, respectively. As seen from the figure, the time required to reach the steady state heat transfer depends on the temperatures that are input to the evaporator section of the HOHP. The heat transfer profiles between the numerical model and the experimental data were very similar, with the differences being 8.7%, 3.8% and 4.6% for the temperatures at the evaporator section of 60, 70 and 80°C, respectively.

Figure 4.38 Compared heat transfer of HOHP from model and experiment at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of water

Figure 4.39 shows the comparisons of the heat transfer profiles from the numerical model and the experimental data under the transient condition of the HOHP with the temperatures at the evaporator section of 60, 70 and  $80^\circ\text{C}$ , the working fluid as ethanol and the inner diameter of 2.0 mm. The figure identifies that the times to start-up for the heat transfer of the HOHP from the numerical model and the experimental data with the temperature at the evaporator section of  $60^\circ\text{C}$  were 500 and 514 s, respectively. The times to start-up for the heat transfer of the HOHP from the numerical model and the experimental data with the temperature at the evaporator section of  $70^\circ\text{C}$  were 600 and 554 s, respectively. The times to start-up for the heat transfer of the

HOHP from the numerical model and the experimental data with the temperature at the evaporator section of 80°C were 700 and 630 s, respectively. Moreover, this figure shows that the times required to reach the steady state heat transfer from the numerical model and the experimental data with the temperature at the evaporator section of 60°C were 1900 and 1786 s, respectively. The times required to reach the steady state heat transfer from the numerical model and the experimental data with the temperature at the evaporator section of 70°C were 2100 and 1880 s, respectively. The times required to reach the steady state heat transfer from the numerical model and the experimental data with the temperature at the evaporator section of 60°C were 2300 and 2142 s, respectively. As seen from the figure, the time required to reach the steady state heat transfer depends on the temperatures that are input to the evaporator section of the HOHP. The heat transfer profiles between the numerical model and the experiment data were very similar, with the differences being 6.0%, 10.5% and 6.9% for the temperatures at the evaporator section of 60, 70 and 80°C, respectively.

Figure 4.39 Compared heat transfer of HOHP from model and experiment at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of ethanol

Figure 4.40 Compared heat transfer of HOHP from model and experimental at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of R11

Figure 4.40 shows the comparisons of the heat transfer profiles from the numerical model and the experimental data under the transient condition of the HOHP with the temperatures at the evaporator section of  $60, 70$  and  $80^\circ\text{C}$ , the working fluid as R11 and the inner diameter of  $2.0$  mm. The figure identifies that the times to start-up for the heat transfer of the HOHP from the numerical model and the experimental data with the temperature at the evaporator section of  $60^\circ\text{C}$  were  $400$  and  $396$  s, respectively. The times to start-up for the heat transfer of the HOHP from the numerical model and the experimental data with the temperature at the evaporator section of  $70^\circ\text{C}$  were  $500$  and  $464$  s, respectively. The times to start-up for the heat transfer of the HOHP from the numerical model and the experimental data with the temperature at the evaporator section of  $80^\circ\text{C}$  were  $600$  and  $520$  s, respectively. Moreover, this figure shows that the times required to reach the steady state heat transfer from the numerical model and the experimental data with the temperature at the evaporator section of  $60^\circ\text{C}$  were  $1700$  and  $1634$  s, respectively. The times required to reach the steady state heat transfer from the numerical model and the experimental data with the temperature at the evaporator section of  $70^\circ\text{C}$  were  $1900$  and  $1818$  s, respectively. The times required to reach the steady state heat transfer from the numerical model and the experimental data with the

temperature at the evaporator section of 60°C were 2100 and 1952 s, respectively. As seen from the figure, the time required to reach the steady state heat transfer depends on the temperatures that are input into the evaporator section of the HOHP. The heat transfer profiles between the numerical model and the experiment data were very similar, with the differences being 3.9%, 4.3% and 7.0% for the temperatures at the evaporator section of 60, 70 and 80°C, respectively.

### 4.3.3 Comparison of heat transfer of HOHP heat exchanger

Figure 4.41 shows the comparison of the heat transfer profiles from the numerical model and the experimental data under the transient condition of the HOHP heat exchanger with the temperatures at the evaporator section of 60, 70 and 80°C, the working fluid as R11 and the inner diameter of 2.0 mm. The figure identified that the times to start-up for the heat transfer of the HOHP heat exchanger from the numerical model and the experimental data for the temperature at the evaporator section of 60°C were 400 and 368 s, respectively; for the temperature at the evaporator section of 70°C were 500 and 456 s, respectively; and for the temperature at the evaporator section of 80°C were 600 and 544 s, respectively. Moreover, this figure shows that the times required to reach the steady state heat transfer from the numerical model and the experimental data for the temperature at the evaporator section of 60°C were 1700 and 1634 s, respectively; for the temperature at the evaporator section of 70°C were 2000 and 1912 s, respectively; and for the temperature at the evaporator section of 80°C were 2500 and 2378 s, respectively. As seen from the figure, the time required to reach the steady state heat transfer depends on the temperatures that are input to the evaporator section of the HOHP heat exchanger. The heat transfer profiles between the numerical model and the experiment data were very similar, with the differences being 3.9%, 4.6% and 4.9% for the temperatures at the evaporator section of 60, 70 and 80°C, respectively.

Figure 4.41 Compared heat transfer of HOHP heat exchanger from model and experiment at  $T_e = 60, 70$  and  $80^\circ\text{C}$  with working fluid of R11 and  $D_i = 2.0$  mm

## CHAPTER 5

### CONCLUSIONS AND SUGGESTIONS

Following the objectives of this research to develop a mathematical model for the transient condition to prediction the heat transfer of the HOHP and to perform an experiment in which a HOHP under various conditions was studied, as well as to apply the HOHP results to the HOHP heat exchanger and design a HOHP heat exchanger from the simulation model, and to solve the equations and processes, the findings were presented in the results chapters. The summary of this thesis is presented in this chapter.

#### 5.1 Conclusions

##### 5.1.1 Conclusions from mathematical model

###### 5.1.1.1 Temperature at pipe wall of HOHP from model

The temperature for the HOHP at the evaporator section of 60°C gave the lowest time to reach a steady state temperature, follow by the temperatures at the evaporator section of 70 and 80°C. The working fluid of R11 gave the lowest time to a steady state temperature, follow by the working fluids of ethanol and water.

###### 5.1.1.2 Heat transfer of HOHP from model

The temperature at the evaporator section of 80°C had the highest heat transfer for the HOHP, follow by the temperatures at the evaporator section of 70 and 60°C. The working fluid of R11 had the highest heat transfer for the HOHP, follow by the working fluids of ethanol and water.

###### 5.1.1.3 Heat transfer of HOHP heat exchanger from model

The temperature at the evaporator section of 80°C had the highest heat transfer for the HOHP heat exchanger, follow by the temperatures at the evaporator section of 70 and 60°C.

### **5.1.2 Conclusions from experiment**

5.1.2.1 The working fluid has the major effect on the heat transfer of the HOHP. The working fluid of R11 was the best working fluid that had the highest heat transfer. The working fluid of R11 had the highest heat transfer when compared to the working fluids of ethanol and water.

5.1.2.2 The temperature at the evaporator section of 80°C was the best temperature that gave the highest heat transfer. The temperature at the evaporator section of 80°C had the highest heat transfer when compared to the temperatures at the evaporator section of 70 and 60°C.

5.1.2.3 The inner diameter for the pipe of 2.0 mm was the best inner diameter that gave the highest heat transfer. The inner diameter for the pipe of 2.0 mm had the highest heat transfer when compared to the inner diameters for the pipe of 1.8 and 1.6 mm.

### **5.1.3 Conclusions from HOHP heat exchanger**

5.1.3.1 The best temperature for the evaporator section from the numerical model and the experimental evaluation to give the highest heat transfer for the HOHP heat exchanger was the temperature at the evaporator section of 80°C, follow by the temperatures at the evaporator section of 70 and 60°C.

5.1.3.2 The results from the comparison of the heat transfer of the HOHP heat exchanger from the numerical model and the experimental data shows that the heat transfer from the numerical model had shorter times to the steady state heat transfer and had higher heat transfers than the results from the experimental evaluation, but the two values were in good agreement.

## 5.2 Suggestions

5.2.1 The simulation codes in this work can be used to predict the temperature and the heat transfer during the start-up operation of a HOHP in the future.

5.2.2 The numerical simulation in this study can be used to predict the temperature and the heat transfer from the working fluids, the temperatures at the evaporator section and the inner diameters of the pipe that are different from this study.

5.2.3 The numerical simulation of the HOHP heat exchanger in this study can be used to design heat exchangers in the future.

5.2.4 In future work, the HOHP can have many applications.

## **APPENDIX**

**APPENDIX A**  
**Example calculation**

### Example calculation

#### Example calculation heat transfer of HOHP from model

Consider the HOHP with the physical dimensions are lengths of the evaporator section  $L_e = 50 \text{ mm}$ , lengths of the adiabatic section  $L_a = 50 \text{ mm}$ , lengths of the condenser section  $L_c = 50 \text{ mm}$ , total lengths of pipe in the evaporator section  $s_e = 850 \text{ mm}$ , total lengths of the condenser section  $s_c = 850 \text{ mm}$ , outer diameters  $D_o = 3.0 \text{ mm}$ , inner diameters  $D_i = 2.0 \text{ mm}$ , diameters of coil  $D_{coil} = 50 \text{ mm}$ , pitch  $p_s = 10 \text{ mm}$  and inclinations angle  $\theta = 90^\circ$ . The temperatures of the evaporator section of  $80^\circ\text{C}$  and the adiabatic section of  $20^\circ\text{C}$ . The heat transfer of the HOHP can be calculated as following:

The equation in calculation the heat transfer of the HOHP as

$$Q_{out}^{new} = \pi D h_c (T_{v,i} - T_{w,i})$$

Where  $D$  is inner diameter of pipe (m).

$h_c$  is convective heat transfer coefficient (J/kg).

$T_{v,i}$  is temperature of vapor ( $^\circ\text{C}$ ).

$T_{w,i}$  is temperature of pipe wall ( $^\circ\text{C}$ ).

Calculated the convective heat transfer coefficient of the cooling water at the condenser section  $h_c$  as

$$h_c = \frac{kNu}{D}$$

$$Nu = C \left[ \frac{\rho v D}{\mu} \right]^n \text{Pr}^{1/3}$$

The value of  $C$  depend on Re

The properties of cooling water at 20°C are

$$k_c = 0.5984 \text{ W/m}^\circ\text{C}, \text{ Pr} = 7.01, \rho_c = 998.2 \text{ kg/m}^3,$$

$$\mu_c = 1002.1 \times 10^{-6} \text{ Pa.s}.$$

From the model we obtained

$$T_w = 21.30^\circ\text{C} \text{ and } T_v = 23.24^\circ\text{C}$$

Calculated Re as

$$\text{Re} = \frac{\rho v D}{\mu} = \frac{998.2 \times 0.3 \times 0.0020}{1002.1 \times 10^{-6}} = 597.66$$

The Re value used to open the  $C$  and  $n$  value from table in Table E4, and has the  $C = 0.683$ ,  $n = 0.466$ .

Then  $Nu$  can be calculated as

$$Nu = C \left[ \frac{\rho v D}{\mu} \right]^n \text{Pr}^{1/3} = 0.683 [597.66]^{0.466} 7.01^{1/3}$$

$$Nu = 25.71$$

Therefore the  $h_c$  can be calculated as

$$h_c = \frac{kNu}{D} = \frac{0.5984 \times 25.71}{0.0020}$$

$$h_c = 6921.13 \text{ J/kg}$$

Calculated the heat transfer of the HOHP from model

$$Q = \pi D h_c (T_v - T_w)$$

$$Q = \pi \times 0.0016 \times 6921.13 \times (23.24 - 21.30)$$

$$Q = 84.36 \text{ W}$$

### Example calculated heat transfer of HOHP from model

The heat transfer of the HOHP from the model equal 84.36 W, then we calculated the heat transfer of the HOHP heat exchanger from the model as following:

From scope of research of the heat exchanger to provide the HOHP heat exchanger can be exchanger heat of 1000W, then calculated the number of turn as

$$N = \frac{Q}{Q_{Theory}}$$

$$N = \frac{1000 \text{ W}}{84.36 \text{ W}}$$

$$N = 11.85 = 12 \text{ tube}$$

The properties of hot water in the evaporator section (80°C).

$$\rho_h = 971.8 \text{ kg/m}^3, \mu_h = 0.000355 \text{ Pa.s}, C_{p,h} = 4197 \text{ J/kg}^\circ\text{C},$$

$$k_h = 0.67 \text{ W/m}^\circ\text{C}, \text{ and } Pr_h = 2.22,$$

The properties of cooling water in the condenser section (20°C).

$$\rho_c = 998 \text{ kg/m}^3, \mu_c = 0.001002 \text{ Pa.s}, C_{p,c} = 4182 \text{ J/kg}^\circ\text{C},$$

$$k_c = 0.598 \text{ W/m}^\circ\text{C}, \text{ and } Pr_c = 7.01,$$

Calculated the maximum heat transfer from the evaporator and the condenser sections as

$$Q_{\max} = C_{\min} (T_{hi} - T_{ci})$$

Calculated  $C_{\min}$ , when  $T_{hi} = 74.27^\circ\text{C}$  (from the model),  $T_{ci} = 20^\circ\text{C}$ ,

$\dot{m}_h = 0.00417 \text{ kg/s}$  and  $\dot{m}_c = 0.00417 \text{ kg/s}$ .

$$C_c = \dot{m}_c C_{p,c}$$

$$C_c = 0.00417 \times 4182$$

$$C_c = 17.4 \text{ W/}^\circ\text{C}$$

$$C_h = \dot{m}_h C_{p,h}$$

$$C_c = 0.00417 \times 4185$$

$$C_c = 17.5 \text{ W/}^\circ\text{C}$$

Then we have the  $C_{\min}$  as

$$C_{\min} = C_c = 17.4 \text{ W/}^\circ\text{C}$$

Therefore we can calculate  $Q_{\max}$  as

$$Q_{\max} = C_{\min} (T_{hi} - T_{ci})$$

$$Q_{\max} = 17.4(74.27 - 20)$$

$$Q_{\max} = 946.50 \text{ W}$$

Calculate the overall heat transfer of HOHP heat exchanger as

$$U = \frac{1}{1/h_e} + \frac{1}{1/h_c}$$

Calculate  $h_e$  at the evaporator section as

$$h_e = Nu_{D,h} \frac{k_h}{D_o}$$

Calculate the velocity of hot water in the evaporator section as

$$v_h = \frac{\dot{m}_h}{\rho_h A_h}$$

$$v_h = \frac{0.00417}{971.8 \times \pi \times 0.005^2}$$

$$v_h = 0.055 \text{ m/s}$$

From calculation the number of tube, we set the  $S_T = S_L = 75 \text{ mm}$  and  $S_D = 62.5 \text{ mm}$ . Therefore we can calculate the maximum velocity as

$$v_{\max,h} = \frac{S_T}{2(S_D - D_o)} v_h$$

$$v_{\max,h} = \frac{0.075}{2(0.0625 - 0.003)} 0.055$$

$$v_{\max,h} = 0.034 \text{ m/s}$$

Calculate the Reynold Number as

$$\text{Re}_{D,\max,h} = \frac{\rho_h v_{\max,h} D_o}{\mu_h}$$

$$\text{Re}_{D,\max,h} = \frac{971.8 \times 0.034 \times 0.003}{0.000355}$$

$$\text{Re}_{D,\max,h} = 282.93$$

The staggered arrangement with the number of tube more than 10 tube, when  $S_T/D_o$  and  $S_L/D_o = 2.5$  we can open  $C_{1,h}$ ,  $C_{2,h}$  and  $m_h$  from Table 2.1 and Table 2.2 and we have  $C_{1,h} = 0.497$ ,  $C_{2,h} = 0.92$  and  $m_h = 0.558$ .

The Nusselt Number of the HOHP heat exchanger at the evaporator section can be calculated as

$$\text{Nu}_{D,h} = C_{1,h} C_{2,h} \text{Re}_{D,\max,h}^{m_h}$$

$$\text{Nu}_{D,h} = 0.497 \times 0.92 \times 282.93^{0.558}$$

$$\text{Nu}_{D,h} = 15.32$$

Therefore  $h_e$  can be calculated as

$$h_e = \text{Nu}_{D,h} \frac{k_h}{D_o}$$

$$h_e = 15.32 \frac{0.67}{0.003}$$

$$h_e = 3420.71 \text{ W/m}^2\text{°C}$$

Calculated  $h_c$  at the condenser section as

$$h_c = Nu_{D,c} \frac{k_c}{D_o}$$

Calculated the velocity of cooling water in the condenser section as

$$v_c = \frac{\dot{m}_c}{\rho_c A_c}$$

$$v_c = \frac{0.00417}{998 \times \pi \times 0.005^2}$$

$$v_c = 0.053 \text{ m/s}$$

From calculation the number of tube, we set the  $S_T = S_L = 75 \text{ mm}$  and  $S_D = 62.5 \text{ mm}$ . Therefore we can calculate the maximum velocity as

$$v_{\max,c} = \frac{S_T}{2(S_D - D_o)} v_c$$

$$v_{\max,c} = \frac{0.075}{2(0.0625 - 0.003)} 0.053$$

$$v_{\max,c} = 0.034 \text{ m/s}$$

Calculated the Reynold Number as

$$Re_{D,\max,c} = \frac{\rho_c v_{\max,c} D_o}{\mu_c}$$

$$Re_{D,\max,c} = \frac{998 \times 0.034 \times 0.003}{0.001002}$$

$$Re_{D,\max,c} = 100.24$$

The staggered arrangement with the number of tube more than 10 tube, when  $S_T/D_o$  and  $S_L/D_o = 2.5$  we can open  $C_{1,c}$ ,  $C_{2,c}$  and  $m_c$  from Table 2.1 and Table 2.2 and we have  $C_{1,c} = 0.497$ ,  $C_{2,c} = 0.92$  and  $m_c = 0.558$ .

The Nusselt Number of the HOHP heat exchanger at the condenser section can be calculated as

$$Nu_{D,c} = C_{1,c} C_{2,c} Re_{D,\max,c}^{m_c}$$

$$Nu_{D,c} = 0.497 \times 0.92 \times 100.24^{0.558}$$

$$Nu_{D,c} = 12.12$$

The  $h_c$  can be calculated as

$$h_c = Nu_{D,c} \frac{k_c}{D_o}$$

$$h_c = 12.12 \frac{0.598}{0.003}$$

$$h_c = 2415.99 \text{ W/m}^2\text{C}$$

Therefore the can be calculated as

$$U = \frac{1}{1/h_e} + \frac{1}{1/h_c}$$

$$U = \frac{1}{3420.71} + \frac{1}{2415.99}$$

$$U = 1415.94 \text{ W/m}^2\text{C}$$

Calculated the area of pipe in heat transfer at the evaporator and the condenser sections can be calculated as

$$A = N\pi D_o (s_e + s_c)$$

$$A = 12 \times \pi \times 0.003 \times (0.85 + 0.85)$$

$$A = 0.19 \text{ m}^2$$

Calculated the NTU as

$$NTU = \frac{UA}{C_{\min}}$$

$$NTU = \frac{1415.94 \times 0.19}{17.4}$$

$$NTU = 15.39$$

The HOHP heat exchanger has staggered flow arrangement can be calculated  $C$  value as

$$C = \frac{C_{\min}}{C_{\max}}$$

$$C = \frac{17.4}{17.5}$$

$$C = 0.99$$

Calculated the effectiveness of the HOHP heat exchanger as

$$\varepsilon = \frac{1 - \exp[-NTU(1-C)]}{1 - C \exp[-NTU(1-C)]}$$

$$\varepsilon = \frac{1 - \exp[-15.39(1-0.99)]}{1 - 0.99 \exp[-15.39(1-0.99)]}$$

$$\varepsilon = 0.94$$

Therefore the heat transfer of the HOHP heat exchanger can be calculated as

$$Q = \varepsilon Q_{\max}$$

$$Q = 0.94 \times 946.50$$

$$Q = 889.0 \text{ W}$$

### Example calculated heat transfer of HOHP from experimental

Consider the HOHP with the physical dimensions as same with the model. The calculation of the heat transfer of the HOHP can be calculated as following:

The equation in calculation the heat transfer of the HOHP as

$$Q = \dot{m}c_p(T_{out} - T_{in})$$

Where  $Q$  is heat transfer of the HOHP (W).

$\dot{m}$  is mass flow rate of cooling water (kg/s).

$c_p$  is specific heat of cooling water (J/kg°C).

$T_{in}$  is inlet temperature of cooling water at the condenser (°C).

$T_{out}$  is outlet temperature of cooling water at the condenser (°C).

The properties of cooling water at 20°C as

$$C_{p,c} = 4183 \text{ J/kg}^\circ\text{C}$$

In experimental of the HOHP we set the mass flow rate as

$$\dot{m} = 0.00417 \text{ kg/s}$$

From the experimental we obtained

$$T_{in} = 20.1^\circ\text{C} \text{ and } T_{out} = 24.8^\circ\text{C}$$

Calculated the heat transfer of the HOHP from experimental as

$$Q = \dot{m}c_p(T_{out} - T_{in})$$

$$Q = 0.00417 \times 4183 \times (24.8 - 20.1)$$

$$Q = 81.98 \text{ W}$$

### Example calculation heat transfer of HOHP heat exchanger from experimental

Consider the HOHP heat exchanger with designed by best working fluid and best inner diameter, we have the physical dimension of the HOHP heat exchanger as length of the evaporator section  $L_e = 50 \text{ mm}$ , length of the adiabatic section  $L_a = 50 \text{ mm}$ , length of the condenser section  $L_c = 50 \text{ mm}$ , total length of pipe in the evaporator section  $s_e = 850 \text{ mm}$ , total length of the condenser section  $s_c = 850 \text{ mm}$ , outer diameter  $D_o = 3.0 \text{ mm}$ , inner diameter  $D_i = 2.0 \text{ mm}$ , diameter of coil  $D_{coil} = 50 \text{ mm}$ , pitch  $p_s = 10 \text{ mm}$  and inclination angle  $\theta = 90^\circ$ . The temperature of the evaporator section of  $80^\circ\text{C}$  and the adiabatic section of  $20^\circ\text{C}$ . The calculation of the heat transfer of the HOHP can be calculated as following:

The equation in calculation the heat transfer of the HOHP heat exchanger as

$$Q = \dot{m} c_p (T_{out} - T_{in})$$

Where  $Q$  is heat transfer of the HOHP heat exchanger (W).

$\dot{m}$  is mass flow rate of cooling water (kg/s).

$c_p$  is specific heat of cooling water (J/kg°C).

$T_{in}$  is inlet temperature of cooling water at the condenser (°C).

$T_{out}$  is outlet temperature of cooling water at the condenser (°C).

The properties of water at  $20^\circ\text{C}$  as

$$C_{p,c} = 4183 \text{ J/kg}^\circ\text{C}$$

In experimental of the HOHP heat exchanger we set the mass flow rate as

$$\dot{m} = 0.025 \text{ kg/s}$$

From the experimental we obtained:

$$T_{in} = 19.8^{\circ}C \text{ and } T_{out} = 27.8^{\circ}C$$

Calculated the heat transfer of the HOHP heat exchanger from experimental as

$$Q = \dot{m}c_p (T_{out} - T_{in})$$

$$Q = 0.025 \times 4183 \times (27.8 - 19.8)$$

$$Q = 836.40 \text{ W}$$

ASHRAE HANDBOOK, 1993

Table E.4 Constant values in calculation convective heat transfer coefficient

$Re_D$	$C$	$n$
0.4 to 4	0.989	0.330
4 to 40	0.911	0.385
40 to 4,000	0.683	0.466
4,000 to 40,000	0.193	0.618
40,000 to 400,000	0.0266	0.805

## **Biography**

## Biography

<b>Name</b>	Mr. Narin Siriwan.
<b>Date of birth</b>	October 17, 1988.
<b>Place of birth</b>	Roi-Et, Thailand.
<b>Address</b>	11 M 10, Phoyai Sub-District, Phanomprai District, Roi-Et Province, Thailand, 45140.
<b>Institution attended</b>	
20011	Bachelor of Mechanical Engineering (Energy), B.Eng. Mahasarakham University, Thailand.
2013	Master of Mechanical Engineering, M.Eng. Mahasarakham University, Thailand.
2016	Doctor of Philosophy (Ph.D.) (Mechanical Engineering) Mahasarakham University, Thailand.
<b>Collaborative internship</b>	2016 School of Chemical Engineering, University of Birmingham, Birmingham, United Kingdom.
<b>Scholarship</b>	Royal Golden Jubilee Ph.D. Program (RGJ-Grant No. PHD/0014/2556).
<b>Contact address</b>	11/10, Phoyai Sub-District, Phanomprai District, Roi-Et Province, Thailand, 45140.
